Degenerative Processes. The narrowing or occlusion of peripheral arteries due to atheromatous plaques of the intima or calcification of the media (Monckeberg's sclerosis) is the most frequent peripheral vascular disease, seen usually in senescence but occasionally in adolescents, particularly if they are diabetic.³¹ So long as myocardial function is sufficient, the increased peripheral resistance is overcome by an increased stroke volume of the heart and by a gradual development of collateral circulation. This state of compensation is mainly endangered by the failing of the cardiac reserve manifested by the falling of blood pressure. It is for this reason that arteriosclerosis with hypotension³² frequently gives rise to peripheral circulatory disturbances. The treatment of these arteriosclerotic patients, who complain of intermittent claudication and later of rest pain, numbness, tingling or burning of the feet, must utilize all the vasodilators, sedatives and physical measures discussed here and also abstinence from tobacco. In addition, the passive vascular exercises, as described by Reid and Herrmann¹⁷ have a real field in developing and sustaining collateral circulation. In my experience the alternating negative positive pressure treatment has been effective, provided the pumping action of the heart is adequate and provided the main arterial channels at the iliac and femoral vessels are sufficiently

patent to permit suction into the ischemic areas below the knee.³² Competent medical management with digitalis and possibly ephedrine may maintain blood pressure at an adequate level.

The diabetic vascular disturbance is primarily on an arteriosclerotic basis, appearing however a decade earlier than in the nondiabetic group.³³ Occlusion of the smaller arteries and arterioles, however, seems to be more frequent in the diabetic group. So it occurs that large areas of skin may become gangrenous resembling a skin infarct, while the larger vessels are pulsating well. A differentiation between diabetic gangrenes of a circulatory or of an infectious basis is very important. While the first group requires major amputations the second group can be treated by incisions or minor amputation.³⁴ The determination of the proper level of amputation has been discussed elsewhere.³⁵

Functional Disturbances—There is an element of spasm in almost every vascular disease in fact there is a certain amount of vasoconstriction a vasoconstrictor tone, in every normal peripheral vessel but chiefly in the lower extremities. Heat, exercise and other stimuli open up these vessels and previously closed collaterals to a maximal degree, failure to dilate, however means an organic lesion.

Vessels, however, may remain spastic continuously or intermittently or they may be exaggeratedly sensitive to cold, fear, anger or anxiety. All these spasms, especially when they occur symmetrically in the two extremities, are usually designated as Raynaud's disease. It is well known, however, that a number of diverse conditions such as tabes, syringomyelia, multiple sclerosis spastic hemiplegia, poliomyelitis, cervical rib, spina bifida, osteo-arthritis of the spine, traumatic perineuritis, polyneuritis and other diseases that I have analyzed elsewhere³⁶ are capable of producing vessel spasms, should they be recognized treatment may be directed against the primary cause. In the present state of ignorance as to the cause of Raynaud's disease, one is forced to call this syndrome a primary vessel spasm, with an increased susceptibility to local stimulation but probably still of central origin. One important postmortem report from Foerster's institute described an organic lesion in the cord with the clinical picture of Raynaud's disease.³⁶

Should no other primary cause be found and should it prove that interruption of sympathetic vasoconstriction by nerve block or reflex heat relieves a spasm and is capable of producing vasodilatation, a sympathetic denervation of the affected part must be considered. Should the vessel spasms be mild, occurring only during the winter, and be easily controlled by lined gloves, boots and the like, the operation is not indicated. When trophic disturbances are beginning to show—and they first are manifest on the nails and tapering of the finger tips—or should ulceration and gangrene be present, a sympathectomy is indicated. A sympathetic denervation of the upper extremity is accomplished by the removal of the stellate, first and second thoracic ganglia with the intervening trunk and ramus, of the

lower extremities by the removal of the second, third and fourth lumbar sympathetic ganglia and the chain. It may well be that this does not constitute a complete sympathetic denervation and that sacral segments may have to be included.³⁷ Both of these operations have several approaches, the method of Gask³⁸ for the upper and that of Adson³⁹ for the lower extremity have been my methods of approach.

Failures from sympathectomy have been frequently observed. When analyzed, they may be due to (1) mistaken indications, (2) insufficient technic, and (3) partial regeneration or neuroma formation. At the present state of knowledge, sympathectomy is advised only in patients exhibiting central or reflectoric vessel spasm. Buerger's disease, arthritis and scleroderma have been excluded from the group. Regarding the technic not only should there be histologic evidence of the removal of the sympathetic chain and ganglia, but a complete removal must be postulated. On the upper extremity the entire stellate ganglion must be excised, and there should be a complete Horner's syndrome, with failure to dilate the pupil with cocaine, on the lower extremity the second lumbar ganglion, which is often covered by the duodenum, must be removed. Many surgeons simply transect the sympathetic chain or remove a small segment. This leads to a third cause of failure, namely, regeneration. The sympathetic trunks regenerate very rapidly unless their trophic ganglion also is removed, hence the importance of removing long segments, together with the ganglia, and of applying alcohol or silver clips to the stumps.

It must be kept in mind that after a powerful vasodilatation of arterioles and capillaries lasting a few weeks, a constriction of the smaller vessels follows, but central or reflex vasoconstriction cannot influence them, only local stimuli. Thus in a patient suffering from Raynaud's disease a digital asphyxia may still develop after a sympathectomy.⁴⁰ But the burning pain that occurs at the end of the attack and is associated with rapid vasodilatation is abolished and no reflectoric vasoconstriction or dilatation can occur.

Very little need be said of the opposite type of functional disturbance, namely, vasoparalysis. Erythromelalgia is the prototype of this disease a very rare condition usually secondary to polycythemia. The extremity is hot and hyperemic, and the pain is relieved by exercise, cold baths and radium packs. In acrocyanosis a paralysis of the small venules is said to exist. There is no satisfactory therapy to date.

This brief survey of the principles of examination, diagnosis and management of peripheral vascular disease should focus some attention on these common and often significant disorders of peripheral circulation. Most of such material is primarily in the hands of the general practitioner, some of them will complicate or obscure the problems of other specialties. A more intensive study of these peripheral circulatory disturbances will lead to earlier and better therapeutic results.

LIMITATIONS OF USE OF SILVER NITRATE IN PREVENTION OF OPTHALMIA NEONATORUM

REPORT OF A SURVEY OF NEARLY 28 000 HOSPITAL BIRTH RECORDS AND 2 000 CASES OF OPTHALMIA NEONATORUM

LOUIS LEHRFELD, M.D.
Ophthalmologist Philadelphia General Hospital
PHILADELPHIA

For fifty years the medical profession has accepted Crede's method for the prevention of ophthalmia neonatorum without dispute. Finding that 2 per cent silver nitrate is too irritating to the eyes of the newborn, physicians in general have reduced the strength of silver nitrate to 1 per cent. Ernst Fuchs in his prize essay of 1884 quotes the statistics of Crede to the effect that 108 per cent of the babies born at the University Clinic and Polyclinic for Obstetrics and Gynecology and School for Midwives at Leipzig had blennorrhea before the use of silver among 2,897 patients, and that following the use of 2 per cent silver nitrate the incidence of blennorrhea dropped to from 0.1 to 0.2 per cent of a total of 1,160 infants. Institutions interested in the blind have recorded a tremendous drop in the number of admissions to the schools for the blind by reason of ophthalmia neonatorum attributing such reduction to the use of silver nitrate.

A survey of the records of the department of public health of Philadelphia for the past fifteen years shows that ophthalmia neonatorum has not materially decreased, despite the generalized application of Crede's method of antiseptics. Mayou¹ reported similar statistics for the city of London, indicating that the disease has not been materially held in check for a period of fifteen years. He reports 760 cases in 1915 and 617 in 1930, a decrease, but not a decided one. In Philadelphia, the reported cases range from eighty-two in 1920, reaching a peak of 130 in 1929 and receding to sixty-seven in 1933. It is interesting to note that, of the Philadelphia cases, 28 per cent were gonorrheal while the remaining were nongonorrheal. Lazar's² reports indicate that 55 per cent of the ophthalmia neonatorum cases investigated were nongonorrheal, the pneumococcus being most frequently found. His records indicate that 35 per cent of the nongonorrheal types show no organisms whatever and he assumes that they were due to chemical irritants, such as silver nitrate. The records of the department of health of Philadelphia show also that a large proportion of the nongonorrheal types were due to irritants, the chief of which is silver nitrate. In the effort to determine why ophthalmia neonatorum has not decreased, an elaborate survey was made in six of the largest hospitals of Philadelphia. Birth records of 28,000 cases were thoroughly studied and 1,500 cases of ophthalmia neonatorum on file in the bureau of health investigated.

Six hundred and thirty-two cases of ophthalmia neonatorum were found on the records among 27,873 infants, an incidence of 2.2 per cent. This record is twenty-two times the incidence rate recorded by Crede. In all the six hospitals investigated, careful prophylaxis

was carried out. Approximately 30 per cent of these cases were gonorrheal in origin. It appears that the Crede method of prophylaxis is not being carried out in Philadelphia institutions as originally described by the founder or that the instillation of one drop of a germicide has been relied on too much with a sense of complacent security.

ANTEPARTUM ANTISEPSIS

The most striking fact of the survey is that expectant mothers known to have gonorrhea have not been actively treated for the disease because of the implicit confidence placed on the efficacy of a single drop of silver nitrate in the prevention of gonorrhea of the

Comparative hospital chart

eyes of the new-born. In no phase of public health is the child knowingly exposed to an infection and then an attempt made to prevent that infection by a single drop of a germicide. This survey points conclusively to the fact that, in hospitals where a careful attempt was made to treat gonorrhea in the expectant mother, the incidence rate of ophthalmia neonatorum was one-fifth that of hospitals where no attempt was made to treat the gonorrhea during the expectant period. At Hospitals A and C, where routine procedure is carried out to discover the presence of gonorrhea during pregnancy, the incidence rate of ophthalmia neonatorum was 7 and 10 respectively per thousand births. In Hospitals B and X the incidence rate was 61 and 36 respectively per thousand births. There is no doubt that gonorrhea in the expectant mother should be treated, not with the view of a cure, but to reduce the

Work done under the auspices of the Department of Public Health Read before the Philadelphia County Medical Society Oct 24 1934

 2 Lazar N. K. Types of Ophthalmia Neonatorum Not Due to the Gonococcus Arch. Ophth. 6 32 (July) 1931

number of organisms present so as to minimize the likelihood of infection of the eyes of the new-born

At the Jefferson Hospital, in the obstetric department under the direction of Prof P B Bland, every case of gonorrhea in the antepartum stage is placed under treatment. Not a single baby born of a mother so treated developed ophthalmia neonatorum. There is no need for further proof that Crede's method is in need of revision to include antiseptics of the expectant mother known to have gonorrhea.

This survey shows that a large proportion of mothers who did not have positive smears delivered babies with positive gonorrheal ophthalmia. This is but a reflection of the need for more deliberate and careful technique in the examination of the expectant mothers for infection. Crede originally recommended vaginal antiseptics, using 2 per cent phenol (carbolic acid) solution. He obtained good results under this method but later abandoned the antepartum antiseptics and proclaimed to the world that one drop of 2 per cent silver nitrate had almost specific properties. Nowhere in medicine has silver nitrate either 1 or 2 per cent, been heralded as a specific gonococcicide. In view of the difficulty of a single drop reaching all infected surfaces Gottlieb and Freedman³ showed definitely that 1 per cent silver nitrate does not have the effect on the gonococcus that is generally believed. This is substantiated by clinical investigation of the hospital records.

At the Philadelphia General Hospital 1 per cent silver nitrate was used in a series of 106 babies and in the majority of instances was accompanied by moderate and sometimes severe irritation of the eyes. In another series metaphen 1 4,000 then increased to 1 2,000, was used on 143 babies and practically all the eyes were free from irritation. In the silver nitrate group, thirteen mothers with positive gonorrhea delivered ten babies whose smears were negative, indicating that a large proportion of babies escape infection even before any chemical is placed in the eyes. There were three positive smears from the eyes of the new-born, two of which developed gonorrheal ophthalmia. The other was prevented by active treatment. In the metaphen series there were ten mothers with positive smears for gonorrhea, all of whom delivered babies with negative smears. One case of ophthalmia neonatorum developed in the child of a mother from whom no smear was taken. Here again definite proof is presented that a large proportion of the babies born of mothers having gonorrhea escape infection, but of those who do not escape, a single application of any germicide no matter how powerful, is insufficient to control or prevent the disease.

COMPULSORY LEGISLATION

Forty-four states in this country require the use of silver nitrate or some other germicide in the eyes of the new-born. Not a single one requires the treatment of gonorrhea in the expectant mother in the prevention of ophthalmia neonatorum. The fundamental principles of all public health measures deal with the control of disease at its source. Yet in ophthalmia neonatorum all health officers are content to wait until the infant has been exposed to the disease and place full reliance on the prevention after exposure. The records of this survey point conclusively to the fact that the control of this disease will depend entirely on the modification of present laws requiring the treatment

not only of gonorrhea but also of all nonspecific infections of the vaginal tract of the expectant mother during the period of pregnancy.

As 60 per cent of the deliveries in Philadelphia are in hospitals and in view of the fact that a greater proportion of maternity cases will in the future be delivered in institutions, it is important that this phase of prevention be adopted, especially for all ward cases.

The survey points conclusively to the fact that the Negro race contributes the larger proportion of the cases of ophthalmia neonatorum and that vaginal antiseptics is particularly important in hospitals in which a large proportion of this race is confined.

CONCLUSIONS AND RECOMMENDATIONS

The following procedures are recommended:

1 Superficial sterilization of the birth canal before delivery of all hospital clinic patients, particularly Negroes.

2 Thorough flushing of the eyes of the new-born with sterile boric acid solution, a 3 ounce (90 cc) solution being used for each eye, followed immediately by instillation of 0.5 per cent solution of silver nitrate. This should be repeated on three successive days. On the fourth and subsequent days during the first two weeks in the hospital or at home, the eyes should be flushed thoroughly by the attending physician with sterile boric acid solution.

3 Compulsory reporting of all cases of ophthalmia neonatorum and the compulsory reporting of the results of the treatment at the end of six weeks.

4 Change in state laws to include prenatal antiseptics.

FATAL ASTHMA

REPORT OF CASE WITH BRONCHIAL MEASUREMENTS

HOWARD M. BUBERT, M.D.

AND

C. GARDNER WARNER, M.D.

BALTIMORE

Sir John Floyer¹ in 1698 first suggested that the pathologic physiology of asthma was, basically, a contraction of the muscles in the bronchial wall. Since that time strenuous efforts have been made to demonstrate changes of a characteristic nature that would offer definite proof of this hypothesis. Physiologic facts brought out by animal experimentation seem to offer evidence, by analogy, that muscle contraction plays a part in the production of an asthmatic paroxysm. Several observers, however, notably Coca,² refuse to accept this as proved.

The evidence in favor of the theory of bronchospasm is ably presented by Alexander,³ who quotes many observations, beginning with those of Haller in 1756. The latter noticed that the lung drew itself together on the application of strong acid. Varnier⁴ in 1779 reported the contraction of the finer air tubes when exposed to certain irritating fumes and liquids. The first definitely to demonstrate bronchial contractility was

Williams⁴ in 1840. He tied a tube containing colored fluid in the trachea of a dog, and on stimulation of the lung tissue with a galvanic current this fluid rose in the tube nearly 2 inches. He was unable to obtain a similar effect by stimulating the nerves of the lung. Later Longet,⁴ using larger animals, namely a horse and an ox, obtained a rise in the column of fluid following nerve stimulation. Volkmann⁴ proved that the reaction occurred also on vagal stimulation in the dog. He demonstrated this by placing a flame near the mouth of the tube, on stimulation the flame flickered and once went out. In 1914 Weber,⁴ by the oncometer method and using proper control preparations, confirmed the observations of Brodie and Dixon⁴ that bronchial constriction played the dominant role in increasing intratracheal pressure when the peripheral end of the sectioned vagus was stimulated.

In 1908 Strümpell⁴ suggested that if definite hypertrophy of the bronchial musculature in asthmatic patients could be shown, it would offer the best direct

true bronchial asthma, studied in the manner mentioned, hence we believe that it is of sufficient importance to report. The clinical data are given in considerable detail because the diagnosis is so frequently questioned in these cases.

REPORT OF CASE

History—A white woman, aged 69, was admitted to the Franklin Square Hospital, Baltimore, Nov. 27, 1929, in the service of Dr. William H. Smith and remained in the hospital until her death, Jan. 15, 1931, a period of one year and forty-nine days. During this time she was seen in consultation by one of us (H. M. B.). Her complaint on admission was shortness of breath.

No definite evidence of allergy was revealed in the family history. A suggestive fact was that her son had had convulsions at the age of 15 months, which were supposed to have been due to a heavy cold.

The patient had had the ordinary diseases of childhood, with no complications or sequelae. She had had two miscarriages. The menopause occurred at the age of 35. There were no significant symptoms pertaining to the cardiovascular, genitourinary, gastro-intestinal or nervous systems.

At the age of 12 years the patient had urticaria. At the time of her admission she was unable to eat fish, strawberries or tomatoes because they caused her to have a skin rash and had done so for years. Sea food also caused nausea and gastro-intestinal discomfort. No other evidences of allergic sensitivity were obtained.

Two years before admission the patient had shortness of breath for one day; this did not recur until the summer before admission. In July 1929, while visiting on a small truck farm, she contracted bronchitis, and this continued for two or three weeks, at which time she noticed a beginning shortness of breath. This recurred almost daily and gradually became more severe. After a few weeks she returned to her home in Baltimore without relief. While on the farm she slept on a feather bed and she stated that chickens were raised as part of the farm activities. Her attacks of shortness of breath continued to become more severe until she was admitted to the hospital by Dr. Smith.

Examination—The patient was markedly dyspneic. She was sitting up in bed and talking with difficulty because of labored breathing. The pupils were small and the examiner made the notation "morphism." The chest was emphysematous in appearance, with the percussion note hyperresonant throughout, auscultation revealed numerous sibilant and sonorous rales with prolongation of expiration. The heart did not appear enlarged on percussion. The apex beat could be neither seen nor felt. The mitral sounds were best heard in the fifth intercostal space, 8.75 cm. to the left of the midsternal line. The blood pressure was 178 systolic, 88 diastolic, and the pulse rate was 120 per minute. There was no pulse deficit. No dependent edema was demonstrated over the extremities or the sacral region. The impression of the examiner was that the case was one of bronchial asthma. He stated however that a blood pressure reading of 200 systolic, 120 diastolic had been previously obtained and that "renal asthma" must be ruled out.

The urine was normal except for the finding of two plus albumin in the first specimen which decreased in a few days to a slight trace and persisted in that amount for a long time. Phenolsulphonphthalein kidney function tests on Dec. 2 and 7, 1929, both gave readings of 35 per cent in one hour. Chemical examination of the blood revealed nonprotein nitrogen, 36 mg., creatinine, 17 mg. and blood sugar, 105 mg. per hundred cubic centimeters of blood. Jan. 18, 1930, the figures were nonprotein nitrogen, 35 mg., creatinine 19 mg., and blood sugar, 102 mg. July 31 the nonprotein nitrogen was 41 mg., the creatinine 18 mg., and the sugar 112 mg.

On admission the patient's temperature was normal, rising to 101 F. the third day but returning to normal the sixth day and remaining there for weeks. Repeated sputum examinations were reported negative for Curschmann's spirals, Charcot-Leyden crystals or eosinophils. One is forced to discount this in view of the technician's lack of experience in studying asthmatic sputums and in view of the further fact that numerous

Fig. 1—A, curve plotted from Huber and Koessler's nonasthmatic material; normal; B, composite curve of the three cases reported by Kountz and Alexander; C, curve plotted from our own case of fatal asthma.

proof of the occurrence of bronchospasm during the paroxysms.

In 1922 Huber and Koessler⁵ introduced a greatly improved method for studying pathologic material from asthmatic cases. This consisted of careful measurements of the different bronchial coats in the lungs of asthmatic patients, as compared with similar measurements in nonasthmatic persons. They studied six cases of alleged fatal asthma in this manner. Rackemann⁶ however has shown that, of the six, only one may be considered as showing the pathologic changes of uncomplicated bronchial asthma. In 1928 Alexander and Kountz⁷ reported three acceptable cases of fatal asthma studied in this manner. These four cases are the only ones thus far reported that may be considered as representing fatal true, uncomplicated bronchial asthma studied by the exact method of Huber and Koessler. The case reported here is, we believe, a fatality from

specimens which appeared microscopically to contain spirals were reported as normal. Several differential white cell counts were negative for eosinophils.

Skin tests were made by one of us (H. M. B.) the cutaneous technique being used. These were negative to all common inhalants and foods.

Course in the Hospital—During the patient's prolonged stay in the hospital the asthma recurred almost daily many times persisting without a break for several days. The provocations were usually quite severe but were controllable by varying doses of epinephrine except in rare instances. A very significant fact was her lack of improvement following the administration of morphine, even though at times doses sufficient to cause drowsiness and, on one occasion pupillary contraction were given. October 26 after a gradual rise during the previous few days, the temperature suddenly rose to 103 F. A note made by the attending physician at the time stated that he felt that pneumonia might be developing. No definite signs were found however, on repeated examinations. Forty-eight hours later the temperature returned to 99 F and after a period of a few days did not rise above this figure any time during the twenty-four hours. There were no further noteworthy changes in the temperature. The blood pressure readings were of interest. During the periods in which the patient was free or relatively free of asthmatic symptoms the systolic pressure varied from 122 to 158 mm of mercury and the diastolic from 63 to 98. During the times that the patient was having severe asthma the systolic pressure varied from 178 to 200 and the diastolic from 120 to 130, a finding at variance with the statements of some observers. An interesting phenomenon noted was that immediately after the administration of epinephrine during severe asthmatic symptoms a rise in blood pressure occurred to be followed by a considerable decrease varying proportionately with the improvement in the asthmatic attack achieved by the medication. This has been aptly called the paradoxical epinephrine reaction. Removal of all feathers and other animal products from the patient's bed was without beneficial effect.

At the request of one of us (H. M. B.) the medical resident who was present when the patient died made the following notation:

"For twenty-four hours prior to her death she presented an ashy appearance. Her asthma grew worse attacks were more frequent and lasted longer while the intervals of comparative freedom between the attacks grew shorter and shorter. Just before death she was given epinephrine in 15 minim doses with but slight relief. About ten minutes before death her blood pressure was 200/110 mm of mercury showing as usual, an increase during an attack. Her heart seemed to do well as no signs of congestion were noted such as edema over the sacrum, excessive sputum or increase in the size of the liver. She became increasingly short of breath gasping for air until comatose. It seemed as though she had suffocated because her heart continued to beat for a few seconds after respiration ceased."

The absence of cardiac failure suggested by the foregoing observation, would seem to be confirmed by the pulse chart which showed a rate of 118 on January 14 and a rate of 114 on the day of death, in spite of a preceding twenty-four hours of terrific respiratory difficulty. At the time of death the patient's temperature was 99 F a figure that had not been exceeded during the previous week.

POSTMORTEM EXAMINATION

Permission for only a partial autopsy was obtainable and this coupled with a very limited amount of time at our disposal, owing to factors over which we had no control precluded our doing much more than removing certain organs for later detailed pathologic study, namely the lungs the heart and the kidneys.

The body was moderately well nourished and showed no signs of marked loss of weight. An incision was made in the midline of the abdomen from the upper part of the manubrium almost to the pubis.

The pleural cavities contained practically no fluid. Both lungs were adherent to the chest wall over their entire surface by fine adhesions which were separated readily by the fingers. Both lungs were markedly and uniformly distended throughout

and were definitely less elastic and less crepitant than usual. No gross nodulations or fibrosis were noted.

The pericardial sac contained about 200 cc of a clear straw-colored fluid. The pericardium was smooth throughout. The heart was small and the musculature appeared to be in good condition. No abnormalities of the coronaries were noted.

The contents of the abdomen were essentially negative on rapid examination. Both kidneys were removed.

Both lungs were generally emphysematous with a few friable fibrous tags on the external pleural surfaces bilaterally. The lungs were acutely distended and a coarse crepitant or crackling sensation was elicited on palpation. There was no evidence of nodular consolidation externally, although the organs felt comparatively heavy.

A sectioned surface presented for the most part irregular sized thickened bronchi embedded in emphysematous lung tissue. The majority of these bronchi were filled with a glistening

Fig 2—A bronchus containing both asthmatic and pneumonic exudate, X30

ing, hyalinized exudate. In some of the small bronchioles there appeared to be a purulent exudate around which there was a halo of consolidation in the surrounding lung tissue. It appeared that this pneumonic exudate had been confined to this region by the hyalinized plugs present farther up in the bronchial tree.

The many sections taken from the lungs showed the same general conditions, the chief one being definite changes in the bronchial walls and lumens. All coats were thickened in this process. As will be seen by the accompanying chart, this was most evident in the smooth muscle layer of the medium sized bronchi. There was some degeneration and desquamation of the epithelium of the mucosa. There was hyalinization of the basement membrane of the epithelium. The submucosa was edematous and infiltrated with lymphocytes and eosinophils. The mucous glands were for the most part hypertrophied. Much of the cartilage in the larger bronchi showed hyalinization. The mucous exudate in the lumen was most characteristic. It appeared in whorls and laminae, richly infiltrated with eosinophilic cells. The alveoli of the lungs showed marked dilatation fragmentation of interalveolar walls and intercom-

munication In some of the small bronchioles a rich leukocytic exudate was seen without fibrin or mucus This exudate was present also in some of the air sacs about the terminal bronchioles This leukocytic exudate offered a marked contrast to the mucous exudate of asthma when the two were observed in the same bronchus, as was the case in several of our specimens (fig 2)

The heart was slightly hypertrophied weighing 400 Gm There was no gross evidence of myocardial fibrosis or valvular lesions The coronary vessels were not tortuous or thickened There was evident hypertrophy of the right side of the heart The myocardium of the right ventricle measured 6 mm in thickness while the left measured 18 mm Microscopically there was a slight increase in the size of the individual muscle fibers There was also a slight increase in the amount of interstitial fibrous tissue No cellular infiltration or vascular thickening was noted

* Most of the bronchial measurements were done by Dr Paul M Schwartz

The kidneys were not unusual Their size and weight were within normal limits On the cut surface the normal architecture was preserved The histologic picture was one of an extremely mild chronic nephritis There was an occasional scarred and hyalinized glomerulus with some slight infiltration of small round cells in the interstitial tissue There was also some mild tubular degeneration but no more than is frequently encountered at autopsy in elderly individuals who were without clinical evidences of nephritis during life

METHOD OF PREPARATION AND STUDY

Numerous blocks were taken from both lungs The majority of these were cut approximately at right angles to the bronchial tree, so that the resulting section would be a cross section of the bronchus This tissue, fixed with solution of formaldehyde, was embedded by the routine paraffin method The sections were cut at 7 microns and stained by hematoxylin and eosin Numerous bronchi were studied and measured according to the method devised by Huber and Koessler⁵ This consists of accurate measurements of the bronchi

and their different layers by means of a (Spencer) eyepiece micrometer Huber and Koessler included not only the muscle layer but also the mucous and subepithelial coats We found that the limits of the latter layers were most difficult to determine clearly, and we felt that they offered little trustworthy information The muscle layer, however, was usually quite distinct and readily measured

The bronchi measured by us varied from 0.4 to 8.875 mm in diameter, outside measurement, as seen in the accompanying table Our means of establishing comparative values for the figures obtained in measuring the muscle layer was to take the mean average of from six to eight measurements of the muscle layer at right angles to the lumen as compared with the average of a similar number of measurements of the outside diameter This was the procedure followed by Huber and Koessler The results of these measurements have been plotted, as shown in figure 1 This shows the relationship between muscle thickness and outside bronchial measurements at a given level

As previously mentioned, Rackemann⁶ has cast doubt on the authenticity of Huber and Koessler's asthmatic material In view of this doubt which we feel is entirely justified, our graph includes the normal curve, *A*, of Huber and Koessler for purposes of comparison, the composite curve, *B*, of the three cases reported by Alexander and Kountz⁷ as fatal asthma and the curve of our own case of fatal asthma, *C*, which is shown as a heavy dotted line

Examination of this graph shows clearly the definite increase in the thickness of the muscle layer in asthmatic patients dying during and as the result of an attack, when compared to the thickness of the muscle layers in the bronchi of similar size obtained from non asthmatic patients This muscular hypertrophy is most apparent in the bronchi from 3 mm to 7 mm in diameter

COMMENT

From a pathologic standpoint the changes observed in the bronchial structures as well as the unusual contents of the lumen coincide with those reported by Huber and Koessler and by Alexander and Kountz In our opinion, whorling and inspissation of mucus, together with the heavy eosinophilic infiltration, are characteristic of bronchial asthma These mucous casts of the small bronchi represent embryonic Curschmann's spirals, which are later coughed up after the relaxation of the muscle spasm They should be present "in situ" in those cases in which death comes during an asthmatic paroxysm

The degeneration of the mucous glands is probably the result of prolonged overactivity The eosinophilic infiltration is as yet inadequately explained The changes in the heart and kidneys in this case were negligible The slight hypertrophy of the right ventricle was to be expected with partial obliteration of the capillary bed by the associated emphysema The manifestations of a mild chronic nephritis with some tubular degeneration appears unrelated to the outstanding features in this case

CONCLUSION

This case offers further confirmation of Huber and Koessler's assertion that the musculature of the bronchi is thickened in asthmatic patients when compared with normal controls

ACUTE COR PULMONALE RESULTING
FROM PULMONARY EMBOLISM

ITS CLINICAL RECOGNITION

SYLVESTER MCGINN, M.D.

AND

PAUL D. WHITE, M.D.

BOSTON

The immediate result of a high degree of occlusion of the pulmonary artery is sudden dilatation of the right ventricle and right auricle, which may best be termed acute cor pulmonale in contrast to the well known cor pulmonale of chronic nature associated with progressive enlargement of the right side of the heart secondary to certain pulmonary diseases. The clinical evidence of the acute cor pulmonale resulting from pulmonary embolism deserves consideration because of the frequency and importance of the condition and of the common difficulty in diagnosis. The growing readiness of surgeons to undertake the operative procedure for the removal of the embolus from the pulmonary artery further emphasizes the importance of establishing the correct diagnosis, and until this can be done the entire procedure must be regarded as extremely hazardous.

During the past two years we have encountered several instructive cases of pulmonary embolism which have shown, we believe, the clinical characteristics of the acute cor pulmonale. We shall herewith report these cases in order to present more clearly than has been done hitherto the clinical condition which we would designate by the term "acute cor pulmonale." A brief preliminary report of our observations without this specific designation was made in 1933.¹

HISTORICAL SURVEY

The literature as illustrated by the papers of Hamburger and Saphir² and of Averbuck³ recognizes the difficult problem of distinguishing clinically between pulmonary embolism and coronary occlusion but offers little in the way of a complete symptomatology that is of assistance in making a positive diagnosis. It is not the type of case in which a postoperative patient abruptly dies that is confusing but rather the instance in which the patient survives the acute attack for hours and days and also the unsuspected case of venous thrombosis followed by pulmonary embolism that is occasionally encountered in routine medical practice. It is our purpose to direct attention to some of the clinical signs found in acute cor pulmonale resulting from sudden occlusion of a large pulmonary artery.

The incidence of pulmonary embolism varies according to the statistics of different writers as Hosoi⁴ indicated when he found after an extensive review of the literature that it was between 0.10 and 0.67 per cent in postoperative cases. In his own series it occurred in one out of every 1000 hospital patients, and Lockhart-Mummery⁵ reported it as one in every 1000 surgical cases. Henderson⁶ found that 6 per cent of the postoperative deaths at the Mayo Clinic between 1917 and 1927 were due to pulmonary emboli. Apparently there is also a geo-

graphic difference, for a survey made by Rosenthal⁷ shows that there had been a distinct rise in the frequency of pulmonary embolism in central Europe between the years 1919 and 1928 whereas the reports of the North American clinics failed to show a similar increase.

Pulmonary embolism is seen clinically most frequently as a complication after operation. It may occur at any time in the postoperative course but is usually observed from eight to fourteen days after operation. Henderson⁶ has noted that there were a few more females in his series of fatal cases than there were males and that the average age was 53.2 years, whereas the average age of all the patients operated on was 42.8 years. The average blood pressures in the cases of pulmonary embolism before the embolism occurred was 138 systolic and 82 diastolic, although a few patients had systolic pressures over 200. Farr and Spiegel⁸ found that the average age of their patients who died of pulmonary embolism was 50 years and that it was 35 years in those with clinically diagnosed pulmonary embolism who recovered. Observations made by Snell⁹ suggest that obesity is a factor favoring the occurrence of pulmonary embolism. Hampton and Wharton¹⁰ report that 50 per cent of their patients died within thirty minutes of the onset of the pulmonary embolism, 25 per cent died within fifteen to twenty-four hours and 10 per cent recovered.

Sufficient evidence is available from clinical experiences and experimental demonstrations to substantiate the opinion that the right heart is considerably involved in occlusion of the pulmonary artery by an embolus. Lockhart-Mummery⁵ stated that the right heart dilated as a result of the sudden strain thrust on it and Sir Gordon Watson in his discussion of the same paper concurred with this opinion. Hamburger and Saphir² have made similar observations in a clinical study of pulmonary embolism. Among the eight cases at the Massachusetts General Hospital in which a pulmonary embolotomy has been performed the pulmonary artery was found to be dilated at the time of operation in all except three. Failure of the right ventricle, a state of shock, and inability of the blood to pass a large obstructing thrombus seem likely explanations in those instances in which the pulmonary artery was found not to be dilated.

The experiments of Cohnheim¹¹, Mann,¹² Underhill,¹³ Haggart and Walker,¹⁴ Moore and Binger,¹⁵ Miller and Rogers,¹⁶ and Gibbon, Hopkinson and Churchill,¹⁷ who have produced pulmonary embolism in animals, likewise demonstrate the sudden burden imposed on the right heart. There is a distinct difference in the changes whether or not the pulmonary artery is completely or only partially occluded, or if only one branch of the artery is occluded. In the first instance the condition proceeds rapidly to a fatal termination unless the occluding factor is removed, in which event recovery may ensue. In the second and third instances it has been shown that no marked change takes place in the general circulation until from 52 to 66 per cent of the pulmonary circulation has been cut off, according to Haggart and Walker,¹⁴ and that there must be from 61 to 86 per cent of the pulmonary artery occluded before there is a fall in systemic blood pressure, according to Gibbon and his associates.¹⁷

The majority of the case reports of pulmonary embolism describe the patient as being in a state of shock with a feeble

ACUTE COR PULMONALE—McGINN AND WHITE

JOUR. A. M. A.
APRIL 27 1935

pulse, apprehension, sweating pallor, dyspnea and a low blood pressure. Cyanosis is frequently present and often extremely marked, whereas in other patients the pallor predominates. Whether or not chest pain is present depends largely on the analysis of the examiner. Nystrom¹⁸ speaks of the patients having a "stitch in the side" and Lord¹⁹ believes that although pain is sometimes present and often referred to the shoulders a considerable degree of the discomfort is due to excessive respiratory distress marked by little or no obstruction to the passage of air. Many cases are described as presenting sub-sternal oppression, but there are few descriptions of the unbearable pain generally associated with coronary occlusion unless a pleural friction rub is present also. Hemoptysis is occasionally reported, not infrequently associated with frothy sputum.

The reports of Farr and Spiegel⁸ and Hampton and Wharton¹⁰ indicate that dilatation of the right ventricle is usually marked and the opinion is generally held that it is the cardiac embarrassment that is an important factor resulting in death. Hall and Ettinger²⁰ have concluded that death is due to mechanical reasons after pulmonary embolism rather than to reflex stimulation of the vagus nerves. The literature contains very few references however to the auscultatory changes in the heart. Lord¹⁹ states that the pulmonary second sound may be accentuated and refers to Litten who has observed a rough systolic murmur in the second left inter-space often accompanied by a thrill. This murmur may be heard all over the anterior thorax and sometimes in the back in the region of the third dorsal vertebra. Lord¹⁹ has also stated that the cervical veins may be greatly dilated and pulsating and that an increase of cardiac dullness to the right can sometimes be demonstrated.

Occasionally a case of pulmonary embolism is reported in which the clinical picture presented is of a neurologic nature such as hysteria or convulsions. These symptoms are explained on the relative cerebral anoxemia. Hampton and Wharton¹⁰ have also described cases in which the abdominal symptoms of distention tenderness and vomiting predominated.

The electrocardiogram may give graphic evidence of the strain that the heart is undergoing following pulmonary embolism. Frommel²¹ has reported his observations on the cardiac rhythm of rabbits in which experimental pulmonary embolism had been produced. The electrocardiograms that he obtained showed four stages occurring in the following sequence first, there was a sino-auricular tachycardia second, changing into auricular fibrillation and, fourth ventricular flutter followed by ventricular fibrillation. Otto²² found that the T waves in dogs became inverted when the pulmonary artery was totally occluded and death of the animal ensued. When the artery was partially occluded the T waves were at first inverted and then slowly became upright and presented a picture similar to that which Otto found in ligating the right coronary artery.

Buchbinder and Katz²³ found no significant variations in the electrical axis deviation of electrocardiograms taken of dogs in which intravenous metallic mercury had been injected and some of which had had the pulmonary artery clamped. They did note aberrations in the ventricular complexes and T wave changes. Krumbhaar²⁴ experimenting on cats found similar changes when the pulmonary artery was clamped and, in addition observed an increase in the size of the P waves, ventricular fibrillation, and auriculoventricular block.

Recently, with the assistance of Dr. Holt Bradshaw of the Anesthesia Department of the Massachusetts General Hospital, one of us (McGinn) has been conducting pulmonary arterial occlusion experiments on cats, the results of which are to be published in detail in a later report. Consistent changes in the T waves of the electrocardiograms after complete occlusion of the pulmonary artery, increased PR intervals, complete heart block and ventricular tachycardia have been observed. Immediately after occlusion of the pulmonary artery, the right auricle and right ventricle become greatly dilated (acute cor pulmonale). A secondary effect of the occlusion is asphyxia, which can by itself cause dilatation of the chambers of the heart. It is difficult to determine whether the dilatation or the asphyxia per se is primarily responsible for the subsequent changes seen in the electrocardiograms. Lundy and Woodruff²⁵ have produced dilatation of the heart chambers of dogs by introducing balloons and then distending them with air. They found changes of the axis deviation in the electrocardiograms and one tracing taken when the right ventricle was dilated, showed inversion of the T wave in lead 3. Many observations have been made of electrocardiograms taken during anoxemia and total asphyxia and frequently alterations in the T waves have been found. Some of the electrocardiograms of asphyxiated cats presented by Lewis and Mathison²⁶ and by Lewis, White and Meakins²⁷ show in addition to previously noted changes, inversion of the T waves in lead 2.

REPORT OF CASES IN PRESENT STUDY

The opportunity has come to us during the last year to obtain observations concerning nine patients suffering from pulmonary embolism and to study electrocardiographic records of seven of these cases. Three of the seven patients have recovered and have provided us with subsequent tracings, while the other four patients died and the diagnosis was confirmed at post-mortem examination.

CASE 1—E. C. a white man, aged 42 married entered the hospital following lower right quadrant pain and nausea of thirty hours' duration. Under gas-oxygen ether anesthesia a gangrenous appendix was removed and drains were inserted. The course after operation was marked by a temperature that daily approached 102 F. On the ninth postoperative day he suddenly had a severe pain in the right lower part of the thorax and respirations became more rapid. The following morning his color was good but he was apprehensive and perspiring and had a pulse rate of 130. The right side of the chest did not expand fully and there were dullness diminished breath sounds and rales at the base. Roentgenograms showed both sides of the diaphragm to be slightly elevated but to move with respiration. There was mottled dullness at the right lower lobe and also mottling around the lung roots. There was no pleurisy, cough or sputum. Four days later a phlebitis of the right lower leg became apparent.

On the thirtieth day after operation he suddenly became dyspneic and complained of substernal distress. The pulse rate rose to 130, and the blood pressure dropped to 90 mm of mercury systolic and 70 mm diastolic. The following day a slight but definite to and fro friction rub was heard at the base of the heart, his color was not good, and the sounds of the heart were of poor quality at a rate of 100. The pulmonary second sound was accentuated and there was an increased pulsation of the pulmonary artery palpable in the second left interspace near the sternal border. The blood pressure rose to 120 mm systolic and 90 diastolic, and the white count rose to 28,000 from 12,800. The next day the friction rub was diminished, there was an increased venous pulse in the neck, fine rales were present at both lung bases, and there were dullness and bronchial breathing at the angle of the right scapula. A third episode somewhat similar to the other two occurred on the forty-ninth day after operation. He complained of substernal discomfort and pain in both shoulders on that occasion.

He was discharged from the hospital ninety four days after his operation. His white count and temperature had continued to be elevated, necessitating cautious supervision of his convalescence. Five months later complete recovery was established and he returned to his office work.

The electrocardiogram (fig 1) taken two hours after the attack on the thirtieth day after operation showed sinoauricular tachycardia at a rate of 130. The ST interval of lead 1 had a slightly low origin and there was a gradual ascent of the ST interval in lead 2. There was a late and definite inversion of the T wave in lead 3. The QRS waves were unusual rather wide S in lead 1, notched QRS in lead 2, and inverted QRS in lead 3. There was a distinct change in the electrocardiogram taken four weeks after the attack (fig 2). Normal rhythm was present at a heart rate of 80. The ST

Fig 1 (case 1)—Three leads two hours after attack of pulmonary embolism

the pathologist to have endometrial polyps and leiomyomas. Her past history revealed four previous hospital admissions, for a peritonissilar abscess in 1911, for removal of a hemangioma of the face in 1922, for cauterization and excision of a growth of the rectum thought to be tuberculous in 1926, and for a proctoscopy in 1930. Physical examination showed no abnormalities except for the pelvic trouble. The blood pressure was 150 mm of mercury systolic and 90 diastolic. No murmurs or enlargement of the heart were noted, the aortic second sound was snapping.

The operation was performed under gas-oxygen anesthesia without untoward incident. For the first seven days after operation the temperature rose in the afternoon but never over 100 F. On the fifth day after operation she complained of tenderness in the left calf but there were no localizing signs of phlebitis. On the sixteenth day after operation and after two days of being up in a chair, she suddenly felt a 'gaseous distress' in the lower left side of the chest and had considerable dyspnea but no pain. There was no cyanosis but she was pale and perspired profusely. Physical examination showed a slightly prominent jugular pulsation, an increased pulsation palpable in the second left interspace over the pulmonary artery, in which area there was also a definite gallop rhythm and a blood pressure of 120 mm of mercury systolic and 70 diastolic. These clinical signs disappeared within thirty-six hours. A portable x-ray film showed the diaphragm to be high on the right, but there were no definite pathologic changes evident in the lung fields.

The differential diagnosis rested at first between coronary thrombosis and pulmonary embolism. Three days after the first episode of dyspnea she had another suffocating attack with pressure most noticeable in the left side of the chest, sharp pain in the shoulder, and a pleural friction rub. This was thought to be the result of another pulmonary embolus causing diaphragmatic irritation. Transitory cyanosis was noted and an apparent phlebitis was localized in the left popliteal space. Despite the critical condition at that time the patient proceeded to a full recovery and was ready for discharge fifty-nine days after operation.

An electrocardiogram (fig 3) made twelve hours after the attack showed sinoauricular tachycardia at a rate of 125, a slightly low origin of the ST interval in lead 1, and a gradual "staircase" ascent of the ST interval in lead 2. There was

deep and late inversion of the T wave in lead 3. There was a Q wave present in lead 3. There was a moderate degree of right axis deviation. An electrocardiogram (fig 4) made six weeks after the attack showed normal rhythm at a rate of 100. The ST intervals in all leads arose at the base line. The T waves were iso electric in all leads and the inverted Q wave in lead 3 had disappeared. The PR interval was prolonged (0.25 second). Slight left axis deviation was present.

CASE 3—J R, a white man, aged 60, married, entered the hospital with the complaint of having had monthly attacks of pain in the right upper quadrant of the abdomen and epigastric soreness for seven months. The attacks came at night and were accompanied by vomiting, jaundice, high colored urine and light stools. The history was unimportant except for a strangulated hernia operated on seventeen years before. Physical examination showed only one abnormality, namely, tenderness on pressure in the right upper quadrant of the abdomen. The blood pressure was 130 mm of mercury systolic and 70 diastolic. Cholecystectomy was done under gas-oxygen ether anesthesia, and a chronically inflamed gallbladder with a large stone in it was removed.

Early in the morning of the eighth day after operation he suddenly became dyspneic and blue black, with moist skin. The pulse rate rose to 120 and the blood pressure dropped to 90 mm of mercury systolic and 70 diastolic. He coughed frequently, although there was no evidence of hemoptysis until some hours later. There was no apparent increase of venous pressure, but the right border of the heart was percussed beyond the right sternal margin. He had no chest pain but stated that earlier in the night there was a cramplike pain in the right lower leg. Prior to this episode he had been doing well except for an afternoon elevation of temperature to 100 F. His postoperative orders had included turning him from side to side every two hours. Roentgen examination showed the right diaphragm to be high and sharply domed. He was placed in an oxygen tent and quickly improved, the blood pressure again reaching its normal level.

On the fifteenth day after operation, while using a bed pan he suddenly became dyspneic and ashen in color, at this time he showed a pulse rate of 120 and a blood pressure of 80 systolic. His neck veins were visible but not greatly distended. He had neither pain nor hemoptysis. He grew rapidly worse and lost consciousness. A pulmonary embolectomy was done by Dr Churchill and a large embolus was removed from the pulmonary artery although the heart continued to beat irregularly for half an hour respirations were not reestablished.

An electrocardiogram (fig 5) made twelve hours after the first attack showed normal rhythm at a rate of 110. There was a low origin of the ST interval in lead 1 and a gradual ascent of the ST interval in lead 2.

In lead 3 there was a Q wave and a definite and late inversion of the T wave. An electrocardiogram taken fifty-four hours after the attack showed the same changes.

Postmortem examination showed the operative wounds of cholecystectomy, appendectomy and pulmonary embolectomy. The right lung was collapsed, soft and gray, and weighed 300 Gm. The corresponding pulmonary artery was filled with a fine elastic partly deep red and partly red gray thrombus measuring 12 cm in length and 3 cm in diameter. The left lung weighed 350 Gm and its arteries contained a few, small, adherent firm clots. There was an area in it, 4 by 3 cm, that was firm and deep red. The heart weighed 320 Gm, the right ventricular wall measuring 3 mm and the left 15 mm in thickness. The valves were normal except for the pulmonary, which was slightly stenosed by the operative suturing. The coronary arteries were normal the aorta showed slight sclerosis, an old

Fig 2 (case 1)—Four weeks after attack

fibrous pleuritis was found on the left side, and the kidneys showed a chronic vascular nephritis

CASE 4—S G, a white man, aged 45, married, came to the emergency ward of the hospital complaining of abdominal pain. Eleven days before entry the patient went to bed because of a severe shaking chill. He awoke the next morning drenched in sweat and with an abdominal pain at both sides of the umbilicus, described as being severe enough to cause him to groan. After two days the pain became localized below the midcostal margin toward the right side, then it disappeared for a few days but returned the night before he came to the hospital. Because of tenderness of the abdomen and a white count of 13 000 he was sent to the hospital medical ward for observation.

On the sixth day in the hospital he had a sudden acute pain in the right side of the chest and examination the following day showed slight dullness and diminished breath sounds at the base of the right lung. Roentgen examination showed obliteration of the right costophrenic angle and limitation of respiratory movement of the right side of the diaphragm, both changes being consistent with a right diaphragmatic pleurisy. The heart shadow showed no definite variation from the normal in size or shape.

On the eighth day tenderness was noted in the right calf, at which point there was a palpable cord that indicated a definite phlebitis. Against orders he got out of bed to go to the lavatory and collapsed on the floor. He complained of substernal pain. Cyanosis was present in the lips and nail beds, and the neck veins were distended. The respiratory and pulse rates and the temperature were elevated. The blood pressure fell to 85 mm of mercury systolic and 65 diastolic. On auscultation a gallop rhythm was heard maximal in the pulmonary region and a pleural friction rub was heard on the right side of the chest. The cyanosis increased despite oxygen therapy and he died about twenty-four hours after his collapse.

An electrocardiogram (fig 6) taken five hours after the attack showed sinus arrhythmia at a rate of 110. The ST interval in lead 1 originated slightly below the base line, and the ST interval in lead 2 arose gradually from below the base line. A Q wave was present in lead 3, and the T wave in this lead was sharply and deeply inverted. The S waves in leads 1 and 2 were rather prominent and wide. The electrocardiogram was repeated ten hours after the attack and showed the same changes.

Postmortem examination showed a large blood clot at the bifurcation of the pulmonary artery, which nearly occluded

Fig 3 (case 2)—Twelve hours after attack

CASE 5—E. C, a white woman aged 57, single entered the hospital with a condition diagnosed as malignancy of the large intestine. Twelve days after admission, under tribrom ethanol and ether anesthesia, an ileotransverse colostomy was performed, extensive carcinoma of the cecum was found.

On the evening of the ninth day after operation the patient was found in a state of shock sweating profusely, pale and with cold clammy extremities a feeble pulse, and rapid respirations. The following afternoon she had an abdominal cramp-like pain with precordial oppression and a sense of suffocation. Shortly afterward she began to perspire profusely, the rates of

pulse and respiration were rapid, and the blood pressure fell to 60 mm of mercury systolic and 50 diastolic. The neck veins were distended. The heart sounds were weak and without murmurs except for the pulmonary second sound, which was markedly accentuated. Abdominal examination showed no abnormalities. She improved the next day, the temperature remaining slightly elevated, the blood pressure rising, and the pulse and respiratory rates decreasing. A few moist rales were heard at the right lung base. Four days later a phlebitis with edema of the right lower leg was found. She continued to improve and was discharged from the hospital forty-three days after admission.

An electrocardiogram (fig 7) made twenty-one hours after the acute attack and on the tenth day after the operation showed normal rhythm at a rate of 105. The ST interval in lead 1 originated slightly below the base line and the ST interval in lead 2 had a gradual upward ascent. In lead 3 there was a deep Q wave and a late and sharp inversion of the T wave.

There was also a deep wide S wave in lead 1. A chest lead, the so called lead 4, showed an inverted P wave and a deep Q wave, as normally, but an upright T wave. An electrocardiogram (fig 8) forty-eight hours after the attack showed a normal rhythm at a rate of 105, low origin of the ST interval in lead 1 and gradual ascent of the ST interval in lead 2. In lead 3 the deep Q wave had disappeared and the T wave was iso-electric. Lead 4 had an inverted P wave, a deep Q wave and an inverted T wave, that is it had returned almost to normal.

CASE 6—A. H., a white man, aged 69, married entered the Pennsylvania Hospital where the diagnosis of benign hypertrophy of the prostate gland was made. Under spinal anesthesia, a transurethral operation was carried out and the patient was discharged thirteen days later in good condition.

The patient remained well for two weeks after leaving the hospital until a "cold" developed which was accompanied by a chill pain in the lower part of the abdomen and slight dyspnea. A few days later while sitting at breakfast, he suddenly became pale and short of breath but had no pain. The following morning he had pain in the left flank and in the left side of the chest, the latter being aggravated by coughing and deep breathing. He remained in bed for a few days during which time he was continuously dyspneic, but the chest pain had largely subsided. He was readmitted to the hospital.

Physical examination showed that the patient was quite ill. He rested quietly propped up in bed but with rapid shallow breathing. There was an ashen pallor to his face with moderate cyanosis and moderate congestion of the neck veins. The breath sounds were bronchovesicular and were diminished at the left base where many fine crackling rales were heard. A pleural friction rub was audible in the left axilla. Examination of the heart showed it to be of normal size with a harsh apical systolic murmur, but otherwise the sounds were clear. The pulmonary second sound was greater than the aortic second sound and the blood pressure was noted to be 108 mm of mercury systolic and 80 diastolic. The liver edge was palpable three fingers below the costal margin and there was slight pitting edema over both tibias.

The patient's condition remained essentially unchanged with the pulse rate varying between 140 and 150 and the respiratory rate between 36 and 44. The day after admission he suddenly became much weaker and died shortly afterward. The differ

Fig 4 (case 2)—Six weeks after attack

ential diagnosis included coronary occlusion, pulmonary infarction and bronchopneumonia

An electrocardiogram (fig 9) made ten days after the acute attack and twelve hours before death showed normal rhythm at a rate of 105, a sagging ST interval in lead 1 with a slightly diphasic T wave, and a diphasic T wave in lead 2. The QRS complex was notched in lead 3 and was followed by an inverted T wave. There was slight right axis deviation. In lead 4 the P wave was iso-electric, and a deep Q wave was present with an upright T wave.

At postmortem examination the body was well developed, with slight edema of the left leg. An organized thrombus was found at the bifurcation of the pulmonary artery, extending to either side with smaller thrombi in the blood vessels of both lungs. The lower lobes of the lungs were markedly congested. The heart weighed 400 Gm, the thickness of the left ventricle being 14 mm and of the right 5 mm. The heart valves showed some calcification but otherwise were not remarkable. The coronary vessels were patent throughout with a few small atheromatous plaques and one or two larger areas of calcification.

CASE 7—A R, a white man aged 48, married, had always enjoyed good health until he sprained his leg while playing tennis. After a few days he resumed his usual activities, but four weeks later he suffered rather acutely from epigastric pain, which radiated up into the left side of the chest and caused pain on respiration for a week. This attack he ascribed to indigestion. Three weeks and again four weeks after that episode he had an attack characterized by a catch in the throat, pounding of the heart, and rapid, difficult respirations. Five days after the second of these "heart spells" he was seen by us in consultation and his heart and lungs appeared to be normal on auscultation and percussion. Fluoroscopic examination showed a full sized heart with a slightly prominent pulmonary artery.

An electrocardiogram (fig 10) made six weeks after the first attack (of "indigestion") and five days after the most recent "heart spell," showed a sinus tachycardia at a rate of 125. The ST interval in lead 1 originated slightly below the base line and the ST interval in lead 2 had a gradual ascent from slightly below the base-line. There was a very small Q wave in lead 3 and an iso electric or very slightly inverted T wave. There was no abnormal axis deviation.

Fig 5 (case 3)—Twelve hours after attack

to the left lower lobe and superimposed on this was a fresh and probably terminal clot. The heart weighed 400 Gm and was normal except for some dilatation and hypertrophy of the right ventricle.

CASE 8—D B, a white man aged 56, married, had always been in good health except for an appendectomy at the age of 32 and a phlebitis of the left leg followed by a good recovery at 52. Six weeks before our examination a phlebitis developed in the calf of the right leg following some work in his garden which had entailed considerable stooping. Contrary to the advice of his physician he continued to be up and about until one week later, when he was seized with sudden oppres-

sion in the anterior part of the left side of the chest. He was restless and apprehensive, had a slight elevation in temperature, and showed an increase in both the pulse and the respiratory rates. It was believed that he was suffering from coronary thrombosis.

Improvement marked his progress until one evening a week later, when he suddenly developed substernal oppression with radiation to the right axilla, accompanied by exhaustion, dyspnea and sweating. In the early morning he became more cyanotic and dyspneic and his condition was very grave. Two

observers heard a high pericardial friction rub and one heard a gallop rhythm at the midprecordium, both conditions disappearing in the course of a few hours. The neck veins were moderately distended and the pulmonary second sound was accentuated and reduplicated. The blood pressure was 130 mm of mercury systolic and 80 diastolic. There were slight dullness and diminished breath sounds in the right axilla at which point a pleural friction rub could be heard. After this acute illness he gained strength rapidly and his condition at the present time is excellent.

Fig 6 (case 4)—Five hours after attack.

An electrocardiogram made seven days after the original attack and nineteen hours after the most recent episode showed normal rhythm at a rate of 90. There was a tendency to low voltage. The T waves were upright in leads 1 and 2 and there was slight late inversion of the T waves in lead 3. There was no abnormal axis deviation. In lead 4 the condition was normal, with a Q wave and inverted P and T waves.

CASE 9—S O, a white woman, aged 61, married, entered the hospital with a condition diagnosed as ureteral stone. Under ether anesthesia a stone was removed from the left ureter. The postoperative course of the patient was satisfactory until the seventh day. At that time while using a bed pan she was overcome by great difficulty in breathing and stated that her chest felt as though somebody were standing on it. She became apprehensive and pale and perspired profusely. Immediate examination of the heart revealed poor sounds at the apex, marked accentuation of the pulmonary second sound and a definite gallop rhythm heard best in the pulmonary area. An examination one hour later showed that the patient's tongue and lips were cyanotic and that the neck veins were not distended and a slight apical systolic murmur was heard. At this time the gallop rhythm had disappeared and the pulmonary and aortic second sounds were of equal intensity. The systolic pressure was 60, and the diastolic pressure could not be determined. She seemed somewhat improved after the acute episode but gradually became weaker and died two and a half hours after the onset of the attack. Permission for autopsy was refused.

COMMENT

The majority of the clinical symptoms of pulmonary embolism as observed in these nine cases are also commonly found in coronary thrombosis, these include chest pain or substernal pressure, elevation in the temperature, pulse and respiratory rates, and white count collapse, sweating and pallor, and a fall in blood pressure. In no case was there an acute pain in the chest except with pleurisy, but there was usually a suffocating sensation accompanied in two cases by pain referred to the shoulders.

Signs—Râles are frequently heard at both lung bases in coronary thrombosis but, if present, are more apt to be confined to one base in pulmonary embolism. Cyanosis, engorgement of the neck veins, and an accentuation of the pulmonary second sound are more common in pulmonary embolism but may also be present when a large coronary vessel is occluded and acute myocardial failure ensues. In the latter case, however, pulmonary edema precedes evidences of right heart failure, which is not true of heart failure from pulmonary embolism (the acute cor pulmonale). Further attention may be profitably directed toward the clinical evidence provided by the failure of the right heart subsequent to pulmonary embolism. On auscultation of the heart we have heard no significant murmurs but frequently we have heard a gallop rhythm differing from that found commonly after coronary thrombosis in that it is most distinct in the second and third interspaces at the left border of the sternum rather than in the apical area. This we believe is most likely due to dilatation of the right ventricle in pulmonary embolism in contrast to the more common dilatation of the left ventricle in coronary thrombosis. We have been unable accurately to percuss the right border of the heart and thus to demonstrate enlargement in that direction. Not infrequently a dilated pulmonary artery in patients with thin chests can be palpated in the second left interspace. In two cases pericardial friction rubs were loudest in the second left interspace and are interpreted by us as probably due to the dilated pulmonary artery or distended right ventricle rubbing against the pericardium or with the pericardium pressing against the anterior chest wall. Churchill²⁰ has recently emphasized the importance of determining whether or not the pulmonary artery is distended or collapsed and has observed

Fig. 7 (case 5)—Three conventional leads and lead 4 twenty-one hours after attack.

at operation that it is occasionally so dilated as to impinge on the under surface of the sternum. In certain cases we feel justified clinically in estimating the relative size of the pulmonary artery.

The presence of engorged and distended neck veins is direct evidence of increased venous pressure resulting

from failure of the right side of the heart and is therefore an important diagnostic sign. There are some cases, however, in which we fail to observe this sign by the time we examine the patient although it undoubtedly is present immediately after the acute occlusion. The most likely reason for this is that the patient is in shock and the blood is not being returned to the right

Fig. 8 (case 5)—Three conventional leads and lead 4 forty-eight hours after attack.

side of the heart under sufficient pressure to distend the neck veins. This may also be the explanation in those cases in which the pulmonary second sound is not accentuated and the pulmonary artery is not dilated. We believe that we are on the way to answer the two questions presented by Churchill²⁰ in his recent paper: first, as to the signs of right heart strain and failure from pulmonary embolism and, second, as to the factors responsible for variations in the size of the pulmonary artery and right ventricle.

Certain other features rather definitely point to pulmonary embolism, as when the attacks follow operation or occur in association with a phlebitis and when there is a pleural friction rub present. These are not specific diagnostic points, for they may occur with coronary thrombosis or pneumonia, but when present together they are extremely suggestive of pulmonary embolism.

Roentgenograms have provided but little assistance during the acute stages of pulmonary embolism. It has been observed that one side of the diaphragm, sometimes both, may be unusually high and dome shaped. If the roentgenogram is taken immediately after the attack, the lung fields are most commonly found to be clear; density corresponding to an infarcted area or fluid of a pleural effusion will appear at later examinations if at all. A study of possible change in the heart size in acute pulmonary embolism has not yet been made.

The electrocardiograms of the first five cases reported herewith are notable because of their similarity. They were all taken within twenty-one hours of the acute attack of pulmonary embolism. The electrocardiographic tracings in cases 6, 7 and 8 were taken at longer intervals after the first attacks: ten days, six weeks and one week respectively, and although not

identical with the first five cases they show some of the same characteristics. The differences in the time intervals may explain the variations.

The changes in the electrocardiograms that seem to us to be significant when they occur in association and that are demonstrated in all the first five cases of the present series are (1) the prominent S wave and low origin of the T wave in lead 1, the ST segment starting slightly below the baseline, (2) the gradual staircase ascent of the ST interval from the S wave to the T wave in lead 2, and especially (3) the Q wave and definite late inversion of the T wave (commonly considered to be of the coronary type) in lead 3. In no case was there left axis deviation whereas on the other hand one case had very definite right axis deviation and others showed a tendency toward right axis deviation by virtue of the S waves in lead 1 and the R waves in lead 3. The heart rates varied between 110 and 125.

In case 6 the electrocardiogram (fig 9) shows a depressed ST interval with diphasic T waves in both leads 1 and 2 and in lead 3 there is a late inversion of the T wave but the Q wave in lead 3 is absent. The rate is 115, and right axis deviation is present. The electrocardiogram of case 7 shows slightly depressed ST intervals in leads 1 and 2, a very small Q wave in lead 3 and a slight late inversion of the T wave. The rate is 120 and there is no abnormal axis deviation.

In cases 5 and 6 a tracing of lead 4 (chest lead) was made with the right arm electrode placed on the precordium and the left arm electrode on the posterior chest wall. In both of these cases the significant finding is an upright T wave the inverted P and QRS waves not deviating appreciably from the normal. On the other hand, with the common type of coronary thrombosis with infarction in the anterior apical portion of the left ventricle, disappearance of the Q wave in lead 4 is characteristic as well as an upright T wave, while in posterior left ventricular infarction the T wave

mortem examination. Electrocardiograms were made in a follow-up study of three other cases, in case 1 four weeks after the attack, in case 2 six weeks after the attack, and in case 5 forty-eight hours after the attack. The first two cases showed in their later records a complete absence of the abnormal electrocardiographic changes of their earlier records, and left axis deviation

Fig 10 (case 7)—Six weeks after first attack and five days after most recent attack.

had appeared. In case 2 the PR interval increased to 0.25 second. In the follow-up electrocardiogram in case 5, taken only shortly after the attack and twenty-seven hours after the first record, the abnormalities have almost but not completely disappeared. The T wave in lead 4 of this tracing is now slightly inverted.

It is not likely that the electrocardiographic changes are the effect of an elevated diaphragm, because the electrical axis is not shifted to the left. The definite right axis deviation in some cases and the tendency to it in others would seem to preclude the possibility of anoxemia of the myocardium causing all the changes observed, although this complicating factor must be given consideration.

It is our thought that, whether or not these electrocardiographic manifestations are pathognomonic of pulmonary embolism, the consistency with which they have been demonstrated in tracings taken soon after acute attacks of extensive pulmonary embolism has been striking. They may aid materially in differentiating between coronary thrombosis and pulmonary embolism, even though when we first encountered them we feared that they might only confuse the issue. That such electrocardiographic changes do exist in the acute cor pulmonale resulting from sudden occlusion of the pulmonary artery must modify interpretations of these changes, as suggestive of coronary disease. Although it is difficult to obtain electrocardiograms in many of these patients, nevertheless such observations, especially including lead 4, are essential, a large series of cases should be available for study.

Finally, it is evident from our case reports that clinical changes, even in the absence of electrocardiograms, may be sufficient to differentiate clearly between pulmonary embolism and coronary thrombosis.

SUMMARY

1 We have presented case histories of nine patients with the acute cor pulmonale secondary to pulmonary embolism, accompanied by electrocardiographic studies in seven of them.

2 The symptoms and signs of extensive pulmonary embolism are variable, but predominating at first are those of shock—namely, collapse, pallor, sweating, apprehension, and a fall in blood pressure—to be followed by reaction to the infarction itself—namely,

Fig 9 (case 6)—Three conventional leads and lead 4 ten days after attack.

remains inverted. Thus the change in the T wave in lead 4 may prove to be of great importance in the diagnosis of the acute cor pulmonale, as yet we have not enough cases on which to base satisfactory conclusions with reference to this point.

Four of the patients on whom electrocardiograms had been made died and an embolus was demonstrated in the pulmonary artery of each one of them at post-

fever and elevation of the pulse and respiratory rates. In none of our cases did we find acute chest pain in the absence of pleural involvement, but most of the patients complained of substernal oppression and suffocation. Respiratory distress was marked in all cases.

3 If the state of shock from extensive pulmonary embolism is not too great, or after it has largely cleared, there may be found signs indicative of the secondary effect of the pulmonary embolism on the heart itself; that is, the acute cor pulmonale (dilatation of the right chambers) attended by pulmonary artery dilatation. Auscultation in our cases frequently showed accentuation of the pulmonary second sound, gallop rhythm heard best in and just below the pulmonary valve region, and in two cases a "pericardial" friction rub with maximal intensity in the region of the second, third and fourth interspaces. Cyanosis and engorgement of the neck veins were common manifestations at some time during the attack. These changes remained for only a short period in some of the cases. Pleural friction rubs were heard frequently.

4 Electrocardiograms taken soon after the occurrence of the pulmonary embolism showed similar changes in five of our patients, and in two others taken some time after the attack they had some of the characteristics although they were less definite. The changes that appear significant are the presence of a Q wave and late inversion of the T wave in lead 3, the rather low origin of the T wave with a gradual staircase ascent of the ST interval in lead 2, a prominent S wave and a slightly low origin of the T wave in lead 1 and an upright T wave (with inverted P and QRS waves) in lead 4. In none of our cases was left axis deviation present at the time of the acute episode, whereas the tracings of two patients showed definite right axis deviation.

Electrocardiograms of two patients taken after recovery showed a complete disappearance of the changes already mentioned, and in a third patient there was almost a complete disappearance of abnormalities in a record taken forty-eight hours after the attack and twenty-seven hours after the first electrocardiogram. All three of these cases showed a change in the axis deviation; one had a prolonged PR interval, and in one case in lead 4 the T wave was reverting to normal (inverted). Our follow-up studies indicate that the electrocardiographic changes are temporary and may disappear within forty-eight hours after the attack of pulmonary embolism.

5 It is probable that the changes observed clinically and the electrocardiographic variations in cases showing the acute cor pulmonale consequent on pulmonary embolism are due in large part to dilatation and partial failure of the chambers of the right side of the heart.²⁹

²⁹ Since offering this paper for publication we have observed five additional cases of acute cor pulmonale. The clinical and electrocardiographic observations coincide with those described.

Good Investments—When American food budgets are studied carefully in the light of the fact that we must purchase mineral elements and vitamins as well as protein and energy, the money spent for fruits and vegetables is found to make its full nutritional return. The growing realization of this has already resulted in giving fruits and fresh vegetables more nearly the place in practice which for scientific reasons we feel that they should hold. They are not luxuries but good investments. They afford us an excellent opportunity to invest our food money in health and pleasure at the same time.—Sherman H. C. Food and Health. New York: Macmillan Company, 1934.

SURGICAL DIATHERMY OF CARCINOMA OF THE RECTUM

ITS CLINICAL END RESULTS

ALFRED A. STRAUSS, M.D.
SIEGFRIED F. STRAUSS, M.D.
ROBERT A. CRAWFORD, M.D.
AND
HERMAN A. STRAUSS, M.D.
CHICAGO

In 1910 Kolischer introduced and advocated surgical diathermy for the removal of inoperable malignant tumors. In 1913 we employed this method for the removal of two cancers of the colon and three of the rectum in very old persons. The results were excellent. For a number of years we used surgical dia-

Fig. 1—Section of an excised scar in which no carcinoma cells are present.

thermy in cases in which operation was impossible—when the tumor was fixed when the patient was very old (in the seventies) or when there was some other contraindication to a radical surgical procedure, such as disease of the heart or lungs. The results in these isolated cases were so satisfactory that for the past seven years we have used the procedure in practically all cases of cancer in the rectum up to the sigmoid colon which could be reached from below by the glass tube method, which we shall describe later.

Clinically, the results of the treatment are remarkable. After the first or second application of diathermy the patient gains weight, and the hemoglobin content and red cell count of the blood are increased to normal.

From the Henry Levy and L. L. Cohen grant to the Stomach Group of the Michael Reese Hospital. The organization of the Stomach Group is as follows: Alfred A. Strauss, M.D., Siegfried F. Strauss, M.D., James Patejdl, M.D., surgery; Herbert Brinswanger, M.D., Jacob Meyer, M.D., medicine; Heinrich Necheles, M.D., physiology; Otto Saphir, M.D., pathology; Robert A. Arens, M.D., roentgenology and from the Surgical Department of the Mount Sinai Hospital.

levels. Even a patient who has lost a great deal of weight or is cachectic loses all the appearances that are characteristic of a person with advanced carcinoma. The gain in weight shown by our patients has amounted to from 15 to 50 pounds (6.8 to 22.5 Kg). This increase in weight, red cell count and hemoglobin content is not temporary. We have observed a number

of six or seven years, and many at the end of three or four years, show no signs of metastasis, loss of weight or cachexia.

Kolischer stated that the electrocoagulation not only produces mechanical destruction of the tumor but causes the throwing off into the circulation of certain substances and antibodies which immunize the patient against further progress of the disease. These substances, in all probability, are similar to the end products of treatment with high voltage roentgen radiation or radium. The reaction may be attributed to an intense stimulation of the reticulo-endothelial system and the consequent local and general phagocytic action of the macrophages. We are investigating this problem by experimentation with animals. We have also made a series of investigations on the blood of patients before, during and after treatment with surgical diathermy in the hope that we might find substances not normally present which would explain the reaction. In a number of instances, moreover, we have placed a cannula in the common thoracic duct, gathering the chyle, in the hope that we might observe chemical changes and secure end products that could be utilized in the treatment of other patients. So far, however, our studies have not shown any changes in the blood or chyle.

The question is whether surgical diathermy inhibits the further progress of the disease along the lymphatics

Fig 2—Section of an excised scar showing dense scar tissue and carcinoma cells

of patients for from three to six years, and they have retained their weight, color and healthy appearance.

In our earlier cases we gave the patient a series of blood transfusions, believing that the blood of young persons has a carcinolytic effect, but in order not to obscure the effect of the surgical diathermy we have not used blood transfusions in the last few years, except when one transfusion was necessary before operation on account of the poor general condition of the patient. We want to emphasize, therefore, that the improvement shown by these patients is not due to other therapy. All the patients received diathermy alone—no treatment with radium or high voltage roentgen radiation and no liver therapy or other measures to increase the red cell count, hemoglobin content or weight. Moreover, the improvement cannot be due to colostomy, which was performed on some of the patients, for twenty-two patients were not subjected to colostomy and they have gained as much weight and look as well as those on whom the operation was performed.

The argument may be brought forth that the patient gains weight because the primary carcinoma is destroyed and therefore there is no absorption of toxins from it. Against this theory is the fact that in many of the cases in which we used surgical diathermy the patient was well along in years and had a large mass which was fixed and practically inoperable and there must have been metastasis at least along the lymph glands in the pelvis. In spite of this, some of the patients at the end

Fig 3—Instruments used in surgical diathermy for carcinoma of the rectum: a, intestinal suction apparatus; b, glass cylinder; c, electrode.

or in distant organs such as the liver. It is our impression that it does. If it did not, surely some of the patients who were treated for advanced carcinoma three or four years ago would by this time show metastasis in the regional lymph glands or in the liver. No evidences of such metastasis have been observed, however. On the other hand, in two cases in which we explored the abdomen on account of symptoms of

disturbance of the bladder, which developed several years after the treatment with surgical diathermy, we removed from the pelvis a few slightly enlarged lymph glands, which contained what appeared to be poorly staining dead carcinoma cells. This indicates at least the possibility that the macrophage and reticulo-endothelial reaction produced by diathermy may have

Fig 4—Technic of surgical diathermy for carcinoma of the rectum. In *a* is shown the electrode with the glass speculum in place; in *b* the suction apparatus in place. *U* indicates the uterus, *Sym* the symphysis pubis and *B* the bladder.

destroyed the carcinomatous cells in the regional lymph glands or rendered them inactive.

In four cases we excised the scar in the rectum resulting from the surgical diathermy by a modified Kraske operation. In one case the excision was made five years after the diathermy treatment, in one, three years, and in two, two years. We allowed what we considered to be sufficient time to see whether there would be local recurrence. The excised scar was examined histologically. In two cases no carcinoma cells could be seen (fig 1), but in the other two there were definite carcinoma cells (fig 2). More than two years have elapsed since the excision of the scar in each of these cases, and there has been no recurrence. The histologic sections appear to consist of degenerated carcinoma cells surrounded by a great deal of connective tissue, according to the pathologist, they looked like dead carcinoma cells. This corresponds to the clinical fact that two years after excision of the scar the rectum is perfectly smooth, even in the two cases in which carcinoma cells were seen in the scar.

END RESULTS AND MORTALITY RATE

Of the forty-two patients whom we have treated by this method, twenty were females and twenty-two were males. A primary colostomy was performed on twenty and a primary ileostomy on one, twenty-one underwent no such operation.

Thirty-two of the patients had a temperature ranging from 100.6 to 103 F. for several days, the fever usually subsided within eight or nine days. Five of the patients had severe hemorrhages, necessitating packing on from the tenth to the twelfth day. In one patient a rectal abscess developed.

Nineteen patients received one diathermy treatment, eleven received two treatments, seven received three, and five received four. Three patients had undergone an operation for cancer, such as removal of the sigmoid or transverse colon, and in these patients the carcinoma of the rectum was probably an implantation carcinoma.

Only two of the patients died within a week or ten days following the first application of diathermy. One was a man of advanced years in whom peritonitis developed, the other, a man of 71, died of bronchopneumonia nine days after the treatment. Two patients died after about a year as a result of sepsis due to infection of the sacrum from too severe diathermy. One patient died three years after the treatment of what was apparently metastasis in the liver. One died of intestinal obstruction due to two previous operations on the transverse colon. Three patients died of pneumonia. One of these, a man aged 68, had been apparently normal for one year, one, for four months, and the third, aged 73, for three years. One patient died of cerebral hemorrhage one year after treatment with diathermy, and one died of a cerebral embolism six months afterward.

Analysis of the foregoing data shows that only two of the eleven deaths can be considered as immediate results of the surgical diathermy, two were due to sepsis occurring as a result of the diathermy about one year after the treatment, and seven were due to intercurrent diseases associated with old age, namely, pneumonia, cerebral hemorrhage and cerebral embolism.

The other thirty-one patients are apparently in excellent condition—one after seven years, two after six years, seven after five years, nine after four years and twelve after three years or less. They have gained weight and do not look like patients with cancer. The fact that twenty-two of them were not subjected to

Fig 5—Excision of scar tissue causing stricture of the rectum following diathermy for cancer and intestinal anastomosis through a modified Kraske incision.

colostomy and have full use of the rectum makes the results obtained by this method compare favorably with those secured by radical surgical intervention.

We have reports of at least twenty-five more isolated cases observed by physicians in various clinics who have used this method with results similar to those that we have described. However, they date back only two years.

THE TECHNIC

In applying surgical diathermy for carcinoma of the rectum we have used the glass tube method. If a sigmoidostomy is performed we use a gridiron incision with a skin flap to hold the sigmoid colon above the skin. We have been using diathermy in more and more cases without a temporary sigmoidostomy. If

Fig 6—Technic of anastomosis of the cut ends of the rectum with silk sutures and an inner layer of continuous chromic catgut suture

the patient is not in good condition a transfusion of 600 cc of blood is given. We have used only nitrogen monoxide and ether for anesthesia. For several days before operation the patient is given daily 1 ounce (30 Gm) of magnesium sulphate in 7 ounces (200 cc) of water divided into sixteen doses, followed by enemas and irrigation of the lower portion of the sigmoid colon, and finally the lower portion of the sigmoid colon and the rectum are emptied by a suction apparatus. We have been able to coagulate satisfactorily tumors from 4 to 6 inches (10 to 15 cm) above the anus, but we think the greatest value of the method is for tumors that lie just above or within the external or internal sphincter, where radical operation would mean the destruction of the rectum and its sphincters. The rectal sphincter can be stretched so as to admit a glass cylinder, which varies in circumference as well as in length, similar to the old vaginal glass speculum (fig 3b), which is passed up the rectum to the carcinomatous area. We use an intestinal suction apparatus (fig 3a), which not only keeps the wound free from blood but aspirates the smoke that is created by the coagulation. The electrode used is a flat, round tip, which is bent at right angles so that it can coagulate all the parts of an annular carcinoma (fig 3c). It is important to have all the electrode except the tip insulated by rubber tubing, so that exposed metal will not coagulate normal parts of the rectum (fig 4).

Early in this work we coagulated too deeply and too thoroughly. We have come to the conclusion of late that it is best to coagulate superficially and not too severely, wait two or three weeks to see how much has been destroyed, and then give a second, third or fourth application, if necessary, at intervals that can be determined by rectal examination. When this method was used, much less stricture and scar formation resulted and in a number of cases there was

practically none. In several of our early cases, in which we coagulated too thoroughly, the coagulation extended into the periosteal tissue of the sacrum and coccyx and produced perisacral infection and osteomyelitis. In two instances sepsis and death occurred within a year. After we recognized this, in the third case we removed that portion of the coccyx and sacrum and the patient recovered. The results in our recent cases, however, have shown that this is unnecessary. In one instance, peritonitis followed the surgical diathermy. In no instance have we observed bladder fistula, bloody urine or injury to the ureters following this procedure. There have been a number of hemorrhages, none of them fatal, which usually came on from eight to twelve days after the treatment, during the period of sloughing. In most instances the hemorrhage was controlled by packing, in two cases it was so severe that transfusion was required.

The technic for the resection of the scar resulting from surgical diathermy by the Kraske method is as follows. An incision is made in the skin over the lower portion of the sacrum and the coccyx, and the coccyx is removed as usual (fig 5a). The levator ani and rectal muscles are dissected away from the rectum by longitudinal splitting (fig 5b). The scar and the narrowed portion of the rectum proper are cut away with scissors transversely (fig 5b). The cut ends of the rectum are then anastomosed with interrupted silk sutures and an inner layer of continuous chromic catgut sutures (fig 6). The wound is closed in the usual manner without drainage. Figure 7 shows an incision (a) and a sagittal section (b) of the scar to be excised from the rectum.

CONCLUSIONS

While the glass tube method of surgical diathermy at first seems rather absurd after consideration of the brilliant results that are obtained all over the world from the radical removal of the lower portion of the sigmoid colon and the rectum for carcinoma of the

Fig 7—An incision (a) and a sagittal section (b) of a scar to be excised from the rectum

rectum, we feel that the excellent results that we have obtained in our experience of seven years and the simplicity with which the procedure can be performed speak in favor of giving the method a thorough trial for a period of five years more, in which we hope to report a much larger series of cases.

We lay great stress on the fact that in twenty-two cases excellent results were obtained without colostomy, the patient having full use of the rectum. We are great believers in the radical and segmental removal of the entire ascending, transverse or descending colon for carcinoma, especially when the continuity of the bowel can be reestablished and the patient can defecate

normally. It is, however, quite another matter to remove the lower part of the sigmoid colon and the rectum and leave the patient with a permanent colostomy opening. While it may be gratifying to the surgeon to demonstrate a series of such cases many years afterward, we do not believe that many of the patients are happy. And how much better it will be if by surgical diathermy the rectum can be preserved with its full physiologic function and the patient can live as long, or almost as long, as the one who has a permanent colostomy opening!

We are particularly interested in the method since it is the first one in which local destruction of, or local application to, a carcinomatous growth has produced, clinically at least, a permanent systemic effect. It seems to destroy the toxins which are absorbed from the carcinomatous tissue, this reaction probably being brought about by an intense stimulation of the reticulo-endothelial system. What the substances are that are liberated into the systemic circulation or into the body by the destruction of the carcinoma by diathermy is an interesting subject for further research.

104 South Michigan Avenue

THE TREATMENT OF ACUTE EMPYEMA IN CHILDREN

PRELIMINARY REPORT

HARRY KOSTER, M.D.
JACOB ROSENBLUM, M.D.
LOUIS P. KASMAN, M.D.
AND
HENRY LERNER, M.D.
BROOKLYN

In eight cases of unilateral empyema in children, the induction and maintenance of an artificial pneumothorax on the sound side was employed to favor drainage and cause earlier obliteration of the empyema cavity. This method was developed following the

Fig. 1 (case 8)—Empyema before intercostal drainage

observation in one case of bilateral empyema that drainage instituted on the side more markedly affected resulted in clearance of the suppuration within seven days. Since this experience was not entirely unique and has been noticed by other observers, it seems that the most likely explanation for the phenomenon

was that the compression of the untreated side by the effusion resulted in more rapid expansion of the lung on the side of which drainage had been established. It then occurred to one of us (J. R.) that perhaps similar acceleration of the healing in unilateral empyema processes could be obtained by reproducing the condition of compression of the normal lung by artificial pneumothorax.

From Crown Heights Hospital

PROCEDURE

Drainage—From seven to ten days after the termination of the active pneumonic process, closed intercostal drainage is instituted, until which time no diagnostic punctures are made. The chest wall is prepared with iodine and alcohol in the region of a point judged to be the most dependent portion of the cavity (usually in the posterior axillary line). Then after infiltration of the chest wall with 1 per cent procaine hydrochloride

Fig. 2 (case 8)—Three days after intercostal drainage and two days after the first pneumothorax

a small incision is made with a scalpel, and a trocar and cannula (26 French) is plunged into the cavity. The trocar is removed and a catheter previously prepared and clamped at one end is pushed through the cannula into the cavity. The cannula is then removed and a rubber diaphragm cap is passed over the tube down to the chest wall. This cap is then sealed to the chest wall with collodion or rubber cement and reinforced with adhesive strapping. The catheter is also strapped securely to the chest wall and subaqueous drainage is provided for with a T tube, one end of which is connected to a reservoir containing 1 per cent surgical solution of chlorinated soda. Beginning on the second or third day the empyema cavity is irrigated every three hours night and day.

OBLITERATING THE CAVITY

From two to three days after drainage is begun, artificial pneumothorax is instituted on the unaffected side of the chest. After proper preparation, the skin and subcutaneous tissues in the sixth interspace in the midaxillary line are infiltrated with procaine and the pneumothorax needle introduced into the pleural cavity. Air is then injected 50 cc at a time, and the intrapleural pressure is noted. We never give more than 250 cc at the first injection nor do we ever allow the positive pressure to exceed 3 cm of water at any time. The needle is then quickly withdrawn, the index finger is applied over the puncture wound and it is sealed with cotton and collodion. In forty-eight hours another 250 to 400 cc is administered. Pneumothorax is maintained by successive injections with roentgenoscopy and fluoroscopy as the guide until drainage has ceased, the lung is expanded and the empyema cavity is obliterated.

OBSERVATIONS

Immediately after the administration of the pneumothorax the patients began to breathe more rapidly and more deeply. The increase in amplitude of respiration was especially noticeable on the side of the empyema (fig. 6). A short time after this a copious purulent discharge from the drainage tube was frequently noted. In a few cases in which the tube was clamped off, pus was forced out round the edges of the tube. In most cases the increase in rate and depth of respiratory movements was unattended by any subjective respiratory distress. In one instance there was moderate dyspnea and this was accompanied by a forceful ejection of pus

Observations in Eight Cases

No	Admission Date	Age	Sex	Onset of Pneumonia	First Sign of Fluid	Intercostal Drainage	Type of Pneumothorax	Days of Fever	Pneumothorax	Days of Drainage	Comment

from the empyema cavity. Two children complained of slight pain in the chest and shoulder for three or four minutes following the administration of pneumothorax.

Following the introduction of the artificial pneumothorax in these cases, the clinical appearance of the

by other methods. In other words "pocketing" was not noticed. The appetite improved very quickly and the children gained weight rapidly. By the fourth day after the introduction of the first artificial pneumothorax, most of the pus had been evacuated from the

Fig. 3 (case 8)—Six days after intercostal drainage

Fig. 4 (case 8)—Eight days after intercostal drainage massive collapse of lung following fourth pneumothorax induction.

Fig. 5 (case 8)—Empyema side almost clear and lung completely expanded twelve days after intercostal drainage was established. There was no drainage for the last three days. Pneumothorax still visible

patient became markedly improved. The temperature fell very rapidly, so that the average duration of fever in the uncomplicated cases was less than seven days. Case 5 was complicated with a suppurative otitis media and the duration of the fever was twenty-eight days. Drainage from the empyema cavity ceased on the seventeenth day. More significant, perhaps, the temperature remained down and it didn't show the periods of remission that are so characteristic of empyemas treated

chest. There was very little drainage at that time and the cavity rapidly became smaller as the lung rapidly expanded. Between the seventh and the tenth day after the introduction of the first artificial pneumothorax, the cavity was usually too small to contain 25 cc of surgical solution of chlorinated soda. The average period until there was no more drainage of pus was 13.7 days after the thoracotomy. The obliteration of the cavity is

demonstrated by comparisons of x-ray films taken before and after the introduction of the artificial pneumothorax (figs 1 to 5) The only complication was subcutaneous emphysema in two cases, which disappeared in from two to four days In case 7 we had an example of what the artificial pneumothorax will do to an encapsulation or pocketing or an encystment of some of the suppurative fluid In this instance there was no drainage and signs were present suggesting a still active pneumonic process This, however, was a faulty interpretation of the condition, because the induction of another artificial pneumothorax quickly caused a very copious drainage with an immediate fall in temperature from 104 to 99, which then continued to stay normal Here the pneumothorax definitely obliterated a small pocket in the process of formation

MECHANISM

Our studies of the mechanism of these phenomena will be reported in a subsequent paper It seems worth while at this time, however, to mention that it has long

Fig 6—Graph obtained by attaching intercostal drainage tube in the empyema cavity and recording the pressure changes by means of a tambour After recording changes at rest and following voluntary forced respiratory movements artificial pneumothorax was induced in the opposite pleural cavity The pressure changes were markedly increased after the pneumothorax

been known that the induction of an artificial pneumothorax in animals was not followed by any change in the total volume of air breathed¹ The unaffected side compensates In our studies of the chest wall movements a similar compensation on the side opposite the pneumothorax is very apparent (fig 6) even though we are dealing with a lung hampered by an empyema

Examination of the x-ray films before and after pneumothorax reveals a shift of the mediastinum toward the empyema side This movement may also contribute to the mechanism of acceleration of cavity obliteration

SUMMARY

- 1 In eight cases of unilateral empyema there was a significant reduction in duration of morbidity
- 2 The cavity was emptied by closed intercostal drainage
- 3 The drainage and obliteration of the cavity were hastened materially by artificial pneumothorax on the unaffected side

POLLEN STUDIES IN SELECTED AREAS

O C DURHAM
NORTH CHICAGO, ILL.

The geographic aspect of fall hay fever in America was noticed long before the role of pollen was established by Blackley¹ in 1873 Daniel Webster, who suffered with ragweed hay fever for twenty years, was symptom free during a season (1839) spent in Scotland Rev Henry Ward Beecher found relief in the Catskill Mountains For more than eighty years, ragweed sensitive persons living in the New England states have fled annually to the White Mountains in New Hampshire In 1872 Wyman² reported favorably on upper Maine, the entire area west of the Mississippi River and most of the area south of Virginia, as being free from fall hay fever In 1875 Judge Gary commented favorably on Mackinac, Mich, and unfavorably on Marquette, Mich³ Local and national organizations have for many years sought by extensive trial and considerable error to list localities favorable for ragweed sensitive persons Often such places have gained good reputations only to lose them after a few years, as the ragweed followed in the wake of civilization

The need of statistical studies on ragweed distribution and on pollen contamination of the air in typical areas bordering the ragweed belt has been apparent for many years Physicians sometimes have occasion to recommend a reliable retreat for the exceptional patient who does not respond favorably to pollen desensitization No statistics on the subject have been published, and those seeking such information have thus been dependent on tradition or the advertising claims of such localities as have established reputations for themselves as havens for hay fever sufferers

In order to investigate the merits of the various localities, it has been necessary first to develop or at least to prove a reliable and practicable method of research The simple "gravity method" of catching and counting pollen suggested by Blackley¹ and widely used by myself and others in the last decade has proved satisfactory for such work It consists in identifying and counting the pollen granules found on a unit area (18 sq cm in these studies) of an oil-coated microscope slide that has been exposed face up for twenty-four hours During the last six years I have used this method in examining more than 15,000 pollen slides uniformly exposed by observers of the United States, Canadian and Mexican weather bureaus

In the nation-wide five year pollen survey (1929 to 1933) my principal effort has been to study the dis-

⁴ Beard G M Hay Fever or Summer Catarrh Its Nature and Treatment New York 1876

tribution and behavior of the various kinds of air-borne pollen in the more densely populated areas. The data from such places are useful to physicians in interpreting skin reactions, selecting suitable pollens for treatment and planning treatment schedules. In the course of this work a number of localities were noted where the atmospheric concentration of ragweed pollen is comparatively low, but no special effort was made to discover other such places.

After five years of satisfactory experience with the cooperation of the weather observers in exposing slides, the investigation was extended during the season of 1934 to the mountain, shore and lake areas where little or no ragweed is found or where comparative or complete relief from ragweed hay fever is reported. Only a limited number of typical locations could be included in the study. As far as possible the exposures were made by regular United States and Canadian weather bureau observers. In localities where no regular weather station is maintained the "cooperative" observers have in every instance given their full support to the investigation. In only two places (Isle Royal and Pikes Peak) was it necessary to depend on persons not connected with weather stations to make the exposures. That the work was carried on this season in the same careful and uniform way as heretofore is attested by the results of the examination of the slides. The presence of dust particles, spores and salt crystals showed that the slides had been faithfully exposed whether pollen appeared or not. Parallel daily variations in the pollen count of neighboring localities give further evidence of the honesty of the exposures. In the single instance in which a serious discrepancy appeared, it was found on investigation that the weather bureau instrument box where the slides were exposed was in a patch of ragweed.

As in previously reported pollen investigations, it is here again emphasized that the figures are only approximate. The amount of air-borne pollen in any locality varies from year to year, depending on wind and weather. For some seasons the amount is twice as much as for other seasons, and the exact reasons for such variation are not always apparent. It may be possible that for some locality the figures here given are not typical, but every effort has been made to obtain the facts. However, records covering even a single season when interpreted in the light of previous experience in scores of other places may be of considerable value. This report is concerned solely with ragweed though at every place investigated a careful count was made of all types of pollen.

The accompanying map shows the number of days in each of eighty-five localities when the air carried an

average of twenty-five or more granules of ragweed pollen per cubic yard. Many hay fever sufferers experience symptoms when there is much less pollen than this in the air, but a smaller amount can hardly be regarded as a severe hazard for the average ragweed sensitive person. In evaluating the results of this survey, however, it is necessary to consider other statistics that those shown on the map, such as maximum concentration and the total amount of pollen found during the entire season. Thus, in some places the data shown in tabular form may present the situation more accurately than that shown on the map. The figures given on the map and in the table are in many cases averages for several years.

Of the eighty-seven localities studied in ten years, only the north Pacific coast stations of Portland and Seattle were entirely free from air-borne ragweed pollen. Ragweeds and related hay fever plants do not grow in this region, and the Cascade Mountains are evidently an effective barrier to pollen being blown in

Comparative severity of the ragweed pollen season in various localities. The figures show the number of days each season in each locality when the air carried twenty-five or more granules of ragweed pollen per cubic yard. Further data in regard to these localities will be found in the accompanying table.

from the intermountain region. California and the Southwest are not greatly troubled with ragweed, as the rainfall is low and the irrigated areas are comparatively small, but other persistent hay fever offenders are present and some pollen is found in the air throughout the year. Three cities in Florida have been found to have comparatively little ragweed pollen—Miami almost none. But Florida as well as California and the Southwest lacks the ideal climate required of summer resorts. The best record in Canada has been found at Prince Albert in upper Saskatchewan—the northernmost station included. Its remote location is probably its greatest disadvantage as a hay fever resort. Winnipeg has had only two days of excessive pollen contamination of the air in four years. In the Great Lakes region, only Port Arthur and Sault Ste. Marie have been studied in previous years. The figures as given in the accompanying table for the latter place, although secured five years ago, compare very favorably with this season's records at adjacent stations.

The unfavorable pollen conditions at Denver, Salt Lake City and Landei, Wvo, should not be considered typical for mountain resorts in that area, but in the present inquiry it has been possible to include only a single Rocky Mountain station. Slides were exposed on Pikes Peak, 9,000 feet above the level of Denver. The season's ragweed total was 982 at Denver, whereas only forty granules were found on top of Pikes Peak.

The ragweed pollen season of 1934 in the North Central and Eastern states was marked by the occurrence of five definite successive storm periods, each with characteristic prevailing south, southwest and westerly winds. The effect of these winds in blowing waves of pollen from the agricultural sections into the forested areas was easily traced in the daily records. The following stations on or near the Great Lakes are

Tampico Mexico	1932	?	?	?	?	2	56	279

* The slide area counted each day is 1.5 sq. cm. The first column under this heading carries the data shown on the accompanying map. The maximum count column records the highest count obtained on any one slide. The last column is the sum of the amounts found on all the slides exposed at a given place throughout its season.

† This figure should be a little larger as the slides were discontinued on September 15. The remaining two weeks would probably have added twenty five or more pollens.

Most of the effort this season was spent on the resort areas of the Great Lakes, New England and adjacent sections. In addition there were three stations on the Gulf of Mexico, one off the North Carolina coast and one in the southern Appalachians. The accompanying table includes data for several cities in the farming region on the south side of the Great Lakes. These are included for purposes of comparison with more favorable places. It may also be noted that such cities as Chicago, Cleveland and Buffalo enjoy only slight advantage over points farther away from the lakes.

known to be in localities where ragweed grows sparingly or not at all. Port Arthur, Ont., Isle Royal, St Ignace and Sault Ste Marie, Mich., Tower, Minn., and Eagle River, Wis. In these places and probably in many others similarly located, ragweed pollen is present in the air in appreciable amounts only when blown in by strong winds from weedy areas in the directions of southeast, south or southwest. One observation of considerable interest is the sharp difference in the pollen content of the air at Duluth and at Tower, Minn., which points are only about 75 miles apart.

The pollen found on Duluth slides was evidently local, while that found at Tower was blown in only on winds from the south. The season total at Tower was only one tenth that at Duluth.

Slides were exposed at the coast guard station on Plum Island, at the end of the Door County peninsula of Wisconsin. The island is wooded except in the immediate vicinity of the lighthouse and coast guard station where ragweed is abundant in all disturbed soil. The slides caught enormous amounts of pollen but there was no way of telling how much of it was from the adjacent weeds and how much came from the upper air.

My previous discovery of low pollen records along the Southeastern sea coast (South Carolina to Florida) suggested that this condition might extend northward to the North Carolina coast or possibly to New Jersey. The results of this study along the Eastern coast are not

very encouraging. A large amount of ragweed pollen appeared on the slides exposed on Hatteras Island, about 10 miles west of Cape Hatteras. At Atlantic City there was more pollen than at New York City. When the wind blows from the ocean at Atlantic City there is very little pollen in the air, but when it blows from the shore the concentration is high. Both on Block Island and on Nantucket Island, pollen contamination of the air is greater than at Boston.

As would be expected, the Catskill and the White Mountain stations show less pollen than is found in the Great Lakes region. The local weather observer at Bethlehem, N. H., reports that ragweed will grow in that locality but that it is kept in check artificially and is not found within five miles of the place of exposure of the slides. The total at Bethlehem was about one-fourth the amount usually found in Boston. From various sources it is reported that ragweed does not grow along the St. Lawrence River east of the north border of Maine, yet even at Father Point, 75 miles beyond the tip of Maine, a small amount of pollen was found. Probably all of it was blown in from a considerable distance.

The only point in the Appalachian Mountains where studies were carried on this season was at Asheville, N. C. Here the condition is no better than that previously found at Knoxville, Tenn. Possibly better places could be found in the mountains of Virginia or Pennsylvania.

In earlier studies the Gulf Coast from southern Florida to Mobile has been found to produce much less ragweed pollen than the coasts of Louisiana and Texas. In this study the condition at Biloxi was found to be similar to that previously found at Mobile, where only north winds bring appreciable amounts of pollen. Galveston and Corpus Christi have about one-half as much pollen as Houston. In both Galveston and Corpus Christi the air is relatively pollen free when winds blow from the ocean, but north winds bring in large amounts of pollen. The season at Corpus Christi seems to occur at the same time as at Galveston and Houston—September and October. The investigation at Corpus Christi was begun July 14, but very little pollen was found before September 15. Here the season does not resemble that at Brownsville where pollen is found from May until November.

A TENTATIVE CLASSIFICATION OF ALLERGIC DERMATOSES

MARION B. SULZBERGER, M.D.

FRED WISE, M.D.

AND

JACK WOLF, M.D.

NEW YORK

The accompanying illustration and table give our suggestion for a schematic and tentative classification of the various common allergic dermatoses. The division is based on (a) the site of the shock tissue (epidermis or cutis) and (b) the length of time required for the development of the visible reaction, after the union of allergen and sensitized tissue.

In each of the first three groups the reaction to skin testing is characteristic, this has served as the criterion

The commoner allergic skin reactions are classified in the table based on histologic localization and on time required for their development. The illustration is made from actual histologic sections of the various reactions. It is schematic only in that it is a composite: the epidermis of a patch test reaction is placed over the cutis of a tuberculin reaction and the superficial changes in the cutis of a wheal reaction are placed over the deeper changes in a case of erythema nodosum.

Classification of Various Common Allergic Dermatoses

- I Eczematous Reactions
 - 1 Site of shock tissue: epidermis
 - 2 Reaction time: twenty-four or more hours
 - 3 Characteristic lesion: spongiosis and intra-epidermal vesicle
 - 4 Causative substances: frequently simple chemicals or products of fungi
 - 5 Type of test: patch test
- II Tuberculin-Trichophyton Type Reactions (not infrequently combined with eczematous responses)
 - 1 Shock tissue: upper cutis, cutis
 - 2 Reaction time: from twenty-four to forty-eight or more hours
 - 3 Characteristic lesion: lymphocyte and later epithelioid cell infiltration
 - 4 Causative substances: usually micro-organisms, bacterial or fungous products (allergy of infection)
 - 5 Test: intracutaneous (forty-eight hours)
- III Urticarial Reactions
 - 1 Shock tissue: upper cutis (blood vessels)
 - 2 Reaction time: from ten to thirty minutes
 - 3 Characteristic lesion: edema, extravasation of fluid and eosinophils (wheal)
 - 4 Causative substances: foods, inhalants, products of micro-organisms
 - 5 Test: intracutaneous scratch or indirect (immediate wheal and flare)
- IV Miscellaneous Reactions (drug eruptions, etc.)
 - 1 Shock tissue: deep cutis, cutis, epidermis, follicles
 - 2 Time: from minutes to days
 - 3 Lesions: (a) nodules, (b) fixed polychromatic areas, (c) multiform dermatoses and follicular lesions, etc.
 - 4 Substances: drugs, micro-organisms
 - 5 Test: usually inconclusive (Sometimes the patch, Moro or intradermal test is of value)

Based on the Symposium on Cutaneous Allergy in the Scientific Exhibit at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 11-15, 1934.

for classification. Thus the atopic dermatoses, including the clinically apparently eczematoid disseminated neurodermites, are classified under the urticarial group III.

Group IV, on the other hand, has no characteristic reaction to the skin test and should be considered as including the miscellany of sensitization dermatoses such as erythema nodosum, multiform erythemas and drug eruptions of various types (for example, fixed eruptions and follicular acneform responses).

It will be seen that this group is heterogeneous, with sensitization as the one common factor. This group, therefore, includes the many as yet unclassified sensitization dermatoses.

The classification must be considered a tentative one, because it rests only partially on established facts, the remainder being based on as yet insufficiently confirmed experimental evidence and in some cases, even on hypothesis. As knowledge of these dermatoses increases it will doubtless be necessary to modify and change various points and certainly to subdivide group IV.

With the rapid progress in the study of allergy, the necessity for such changes may soon become apparent. Nevertheless, it seems to us that the table submitted represents a concise and tenable classification of sensitization dermatoses which is not in contradiction to any at present established facts. Such a presentation may prove of aid in the understanding, teaching and further study of these conditions.

Many points that were apparently without even a hypothetic explanation seemed to us to become amenable to working hypotheses when regarded from the point of view established in the table. For example, in the case of the eczematous contact dermatoses, it is logical to suppose that, if the epidermis is the shock tissue, certain substances coming into contact with the skin from without will be more capable than others of reaching the living epidermal cells in sufficient concentration to produce epidermal sensitization. Keratolytics and detergents, which destroy and/or remove the fatty and horny covering, are obviously prone to be epidermal sensitizers and thus common eczematogenous noxae. The plant oils that can become dissolved in the fatty substances of the skin surface are more likely to produce contact dermatitis than the fat-insoluble protein fractions of the plants. The fungi that produce eczematous dermatophytosis and dermatophytids live in the horny layer and, when absorbed, their products must reach first and in highest concentration the living cells of the epidermis. The dyes, such as paraphenylenediamine, with their propensity for fixation to horny substance, will also achieve a prolonged and intimate contact with the epidermis. The solutions of metallic salts, with their rapidly moving ions of small dimension, may be supposed to possess a greater facility for penetrating the protective covering of the epidermis than solutions or colloidal suspensions of larger particles. The local anesthetics such as procaine and butesin, with their affinity for ectodermal structures, may be inclined to adhere most intimately to the epidermis.

It is known that all the substances mentioned frequently cause contact eczema. Thus, the mere recognition of the fact that the epidermis is the shock tissue in contact dermatitis serves to give a hypothetic explanation of the eczematogenous nature of many apparently unrelated substances and serves as a guide in the selection of probable causes in a given case of contact eczema of unknown origin.

Similarly a consideration of the tabular classification in groups II and III will thus indicate the noxae that must be suspected in each group. Furthermore, the table designates what is to our minds of at least equal importance, namely, the specific technic of testing that must be employed in each group.

The various possible combinations of these types of sensitizations may, of course, be found in one and the same individual. Such combinations are perhaps no more frequent than is to be expected from the laws of mathematical probability.¹

200 West Fifty Ninth Street

PAPILLEDEMA IN UNDULANT FEVER

REPORT OF CASES

C. W. RUTHERFORD, M.D.

IOWA CITY

Papilledema is found as an occasional ocular complication in some diseases in which the symptomatology is so indefinite that a diagnosis can be made only after exhaustive clinical and laboratory studies. Undulant fever is such a disease and it has given rise to choked disk in some cases in which the central nervous system is involved. One such case was found in the domestic literature and four cases in that of foreign countries. Three cases, two of them with necroscopic data, are added in this report. Undulant fever should be considered in the differential diagnosis in cases of obscure etiology in which the optic disks are edematous.

Undulant fever, often called Malta fever, was first accurately described by Marston in 1861 as Mediterranean remittent or gastric remittent fever. The name "undulant fever," proposed by Hughes in 1896 is authorized in the accepted nomenclature of diagnoses. The etiologic agent (*Brucella*) was demonstrated by Bruce in 1887. Recently the name "brucellosis" has been gaining favor in terminology because the designation undulant applies to only one form of the disease. The first report of a case of undulant fever in the United States was made by Musser and Sailer in 1898.

Brucella abortus was isolated from infected cows by Bang in 1897, but it was not until 1918 that Evans called attention to the laboratory similarity of that organism and the organism of undulant fever. The first diagnosis of human infection with *Brucella abortus* was made in Johns Hopkins Hospital in 1922, the case was reported by Keefer two years later. Subsequent studies established the liability of man to contract the disease from animals. Undulant fever is a public health problem.

The organisms of undulant fever occur as coccoid, intermediary oval and bacillary forms, they are from 0.3 to 0.5 micron wide by 0.6 to 1.5 microns long, they are nonencapsulated and nonmotile and are decolorized by Gram's method. There are three varieties: (1) *Brucella melitensis* variety *melitensis* (Bruce) affects goats and is called caprine, (2) *Brucella melitensis* variety *abortus* (Bang) affects cattle and is called bovine, and (3) *Brucella melitensis* variety *suis* (Traum) affects swine and is called porcine. There are also equine, avian and other strains.

¹ A more detailed discussion of other points in connection with three common types of sensitization dermatoses will be found elsewhere (Coca, A. F. Specific Diagnosis and Treatment of Allergic Diseases of the Skin, J. A. M. A. 103:1275 [Oct. 27, 1934]).
From the Department of Ophthalmology, State University of Iowa Hospital and College of Medicine.

Differentiation among the three varieties is made in the laboratory. A medium of fresh beef liver infusion agar is prepared and then adjusted to a pH of 6.6. The addition of thionin 1:25,000 inhibits the growth of the variety abortus but not that of the variety suis. The addition of basic fuchsin 1:25,000 or of methyl violet 1:100,000, or of pyronin 1:200,000 inhibits the growth of the variety suis but not that of the variety abortus. In these tests the container must be sealed and 10 per cent of the air replaced by carbon dioxide. None of the additions inhibit the growth of the variety melitensis. The variety suis is more virulent for man than is the variety abortus.

The disease occurs in ambulatory, mild, undulant, intermittent and malignant forms. The average incubation period is from eighteen to twenty-one days. The onset is usually insidious but may be sudden. Prominent symptoms are weakness, sweating, chilliness, anorexia, headache, fever and loss of weight, other symptoms of varying frequency are constipation, nervousness, cough, rigors, insomnia, general pains, localized pains in the back, joints, abdomen and back of the neck, leukopenia, palpable spleen and abdominal tenderness. The course is generally prolonged and marked by intermissions and remissions. The disease is a very deceptive one. Differentiation must be made from Rocky Mountain spotted fever, tularemia, typhoid, paratyphoid fever, malaria, bronchitis, bronchial pneumonia, rheumatic fever, tuberculosis, subacute bacterial endocarditis, pyogenic septicemia, visceral leishmaniasis, tertiary syphilis, neurasthenia, Hodgkin's disease and influenza. Lemaire called attention to the close clinical similarity of tuberculous meningitis and melitensis meningitis.

The diagnosis is difficult. It is not enough to know that a patient has handled animals or their products or has consumed such products and that the agglutination test is positive. Blood from a patient who has undulant fever may contain no serum agglutinins for that disease, and blood from a symptomless individual may contain serum agglutinins for it. However, the agglutination and intradermal tests should be made. Mononuclear pleocytosis is a prominent feature in the cerebrospinal cases. The diagnosis, in such cases, should be based on (1) finding the organism in the spinal fluid, (2) proving the pathogenicity of the organism for guinea-pigs by inoculation of not less than 10 cc of spinal fluid, and (3) differentiating the species of the organism by the dye tests previously mentioned. Spinal fluid and blood should be cultured for thirty days unless positive growth occurs in less time.

The first record of papilledema in undulant fever was made by Lemaire¹ in 1924. The pressure of the cerebrospinal fluid was increased and both optic disks were congested. The duration of the disease was approximately two and one-half months. The fundi were restored to normal.

Cohen Boulakia² reported a case in which there was an early appearance of optic neuritis. Eight days later the elevation of the disks was increased and there was generalized retinal edema. Intra-ocular hemorrhages occurred. Postneuritic, almost complete optic atrophies followed. The retinas became very pale and later

almost completely detached. This author referred to a case seen by Levy and Uzan.³ Their patient had bilateral papilledema. One and one-half months later the margins of the disks were sharp and the retinal vessels were normal. There was no recurrence in two years of observation.

Orloff⁴ recorded a case in which there was a neuroretinitis of the left eye. The phenomenon was more developed eight days later and there were also general edema of the retina and punctate hemorrhages. Ten days later the fundus could not be seen because of diffuse hemorrhages. The end results were optic atrophy, glaucoma and blindness of the affected eye.

Godwin⁵ reported a case of two and one-half months' duration with papillitis on the right side and a blurred disk on the left side. Transient improvement was followed in three months by a recurrence.

REPORT OF CASES

Diagnoses of undulant fever were made in sixty-three patients admitted to the University Hospital from June 1927 to August 1934 inclusive, of these, thirty-eight were men and twenty-five were women. Three of the series, all white men aged from 20 to 27, showed disk changes. The three were admitted within a period of fifteen months.

CASE 1—J. N., aged 20, was admitted, June 16, 1931. The fundi showed early bilateral papilledema. Central visual acuity was normal. The right field was contracted nasally and the left concentrically with the greatest contraction temporally, the effect was that of a left homonymous contraction. The blood Wassermann reaction, cephalography and ventriculography were negative. The spinal fluid was under increased pressure and contained 1,240 cells per cubic millimeter, a culture was taken but no growth occurred. A diagnosis of epidemic encephalitis was made. The papilledema had receded somewhat by August 15, there were then 235 cells per cubic millimeter of spinal fluid. The fundi were normal, Jan. 2, 1932 and the cell count was 150 per cubic millimeter, 146 being lymphocytes. The fields were normal, February 12. The spinal fluid contained 151 cells per cubic millimeter, July 20. Death occurred suddenly, August 10. Necroscopic diagnoses were (1) melitensis meningo-encephalomyelitis, (2) subacute combined sclerosis (3) mycotic aneurysm of the basilar artery with rupture and (4) subarachnoid hemorrhage. The agglutination test on postmortem blood was positive for undulant fever. The postmortem blood culture was negative.

CASE 2—D. Y., aged 24, was admitted Oct. 7, 1931. The illness began Dec. 24, 1930, with a tingling sensation of the right foot. The sensation spread upward and involved the entire right side of the patient. The attack had a duration of about thirty minutes. A headache along with pain in the neck began about fifteen minutes later. The patient subsequently had similar attacks at intervals of two or three weeks, with indifference as to the side involved. Later on he had attacks of unconsciousness which would last as long as two days. He had a mild elevation of temperature all of this time except for a period of one and one-half months during which he was being given serum intravenously. Sight and hearing were affected when he had headaches. There had been attacks of diplopia when looking toward either side. He had several lumbar punctures, each of which relieved the symptoms temporarily.

Sanders⁶ made an early report of this case and set forth several interesting observations. For three months following the first attack there were several similar attacks but none were severe enough to prevent him from working. A lumbar puncture was made, March 20, 1931. The spinal fluid, which

5 Godwin, D. E. Optic Neuritis in Malta Fever. Am. J. Ophth. 12:747 (Sept.) 1929.
6 Sanders, W. E. Undulant Fever Meningitis. J. Iowa State M. Soc. 21:510-511 (Sept.) 1931.

was under increased pressure, was cloudy and contained a few extracellular, gram-negative organisms. The cell count was over 300, about 36 per cent of the cells were lymphocytes. The patient was admitted to the Johns Hopkins Hospital, where a diagnosis of subacute meningitis or encephalitis was made. An organism resembling that of undulant fever was grown from the spinal fluid.

Some months later the patient was admitted to the University Hospital. The nasal margins of both disks were blurred, October 30. A large hemorrhage above the right disk extended down into the disk, numerous preretinal hemorrhages were scattered throughout. Many large hemorrhages were present in the left fundus, one, a large preretinal hemorrhage, spread off in a fan-shaped figure from the macula. Some perivascularitis was observed.

A lumbar puncture was made November 1. The spinal fluid was under increased pressure and was bloody, there were 900,000 red blood cells and 5,000 white blood cells, 90 per cent of the latter were polymorphonuclears. At the same time a blood count showed 4,500,000 red blood cells and 16,000 white blood cells.

The clinical diagnosis of undulant fever was supported by laboratory methods. The patient went into convulsions, October 26, and died November 3. Necroscopic diagnoses were (1) brucella meningo-encephalitis from *Brucella melitensis* variety suis, (2) mycotic aneurysm of the basilar artery, (3) cerebral hemorrhage, (4) internal hydrocephalus, (5) granular ependymitis, (6) chronic suppurative encephalitis and (7) hydrops of the peripheral cranial nerves.

The bacteriologic and pathologic aspects of this case have been reported by Hansmann and Schenken.⁷ They state that they were unable to find any other case of *melitensis* meningitis of porcine origin in the literature.

CASE 3—E C L., aged 27 was admitted, Sept 15 1932. Central visual acuity was normal. The fields were contracted and only the nasal borders of the blind spots were shown by 1/1,200 on the Bjerrum screen. The patient had papilledema of 15 diopters in each eye, the retinal arteries were small. The blood and spinal fluid were negative to the Wassermann reaction. The blood count was a low normal. Roentgen examination was essentially negative. The department of neurology found a localization for tumor or its equivalent in the left frontal lobe. The patient left the hospital three days after being admitted.

The department of neural surgery of the Mayo Clinic kindly furnished notes on the case. Right papilledema was from 2 to 3 diopters and left was from 3 to 4 diopters, September 26. These had subsided by November 28. Right papilledema was 3 diopters and left 2 diopters, December 13. Both were 3 diopters, Jan 28, 1933. Ventriculographies done Sept. 21 and Dec. 22, 1932, were negative. A parietotemporal exploration was made, Jan 14, 1933, no pathologic changes were found. The spinal fluid was examined Oct 5 and Dec 1, 1932, and Jan. 9, 1933. The number of lymphocytes was 91, 242 and 61, and of polymorphonuclears 19, 8 and 144 for the respective dates. The fluid was under increased pressure at each of ten punctures. The gold curves were normal. The Wassermann reaction was negative. White blood cells numbered 8,000, Sept 23, and 6,100, Dec. 28, 1932. Agglutination tests for undulant fever were positive. Intradermal tests and cultures made on the spinal fluid were negative.

The final diagnosis was *melitensis* meningo-encephalitis with residual hemiplegia.

COMMENT

Melitensis infection of the central nervous system occurs occasionally with or without ocular complications. This report is concerned only with those cases in which papilledema was found.

A summary of sixty-three cases of undulant fever shows that in three there were bilateral papilledema, an increase in the spinal fluid pressure, mononuclear pleocytosis and evidence on which to base a diagnosis of infection of the central nervous system by some

variety of the *melitensis* organism. Five cases were found in the literature, the disk changes observed in them can be interpreted as papilledema.

The diagnosis of undulant fever is admittedly difficult. Papilledema is occasionally found in patients in whom the symptomatology is indefinite and leading signs are absent. It is in such cases that undulant fever should be considered in the differential diagnosis.

University Hospitals

CIRCUMSCRIBED MYXEDEMA

E W NETHERTON, MD

AND

B E MULVEY, MD

CLEVELAND

In 1895 Watson-Williams¹ described a case of exophthalmic goiter in which there was a patch of persistent hyperemia on each leg and also referred to a similar case, which had been observed by Hektoen. Morrow² observed a patient with generalized myxedema who improved under treatment with thyroid extract but later had exophthalmic goiter and symmetrical areas of solid edema of the legs. Subsequently reports of this comparatively rare condition have appeared from time to time in foreign medical literature.

O'Leary³ in 1930 made the first comprehensive contribution on this subject in the American medical literature. He described eight cases in which there were plaques of localized myxedema of the skin on the legs. In seven instances the lesions developed following a recurrence of hyperthyroidism and in one case the myxedematous plaques preceded the symptoms of exophthalmic goiter. One year later Pillsbury and Stokes⁴ reported three additional cases and gave a tabular summary of twenty-two obtained from a thorough review of the literature. Additional cases have been reported by Ingram,⁵ Lord and Morrison⁶ and McMenemey.⁷ Thomas⁸ reported an unusual case of clubbed finger with subperiosteal new bone formation in a Negro following subtotal thyroidectomy for hyperthyroidism. A brown edema of the legs similar to the condition under discussion was associated with the bone changes. At the meeting of the Cleveland Dermatological Society, June 14, 1934, an identical case was presented from the dermatologic service of Lakeside Hospital.

In view of the paucity of reports on this subject, it seems worth while to record the following six cases of circumscribed myxedema of the skin, which have been observed at the Cleveland Clinic.

REPORT OF CASES

CASE 1—A married woman, aged 65, admitted to the clinic, Jan 15, 1925, complained of loss of weight, nervousness, sweat

ing, palpitation of the heart, weakness, and an enlargement of the neck. She had been in failing health for five years.

The patient was thin, asthenic and poorly nourished. The thyroid gland was enlarged and nodular. The patient displayed a moist skin, a faint systolic murmur at the base of the heart and a mild but persistent tachycardia. The clinical diagnosis was hyperthyroidism, and thyroidectomy was performed January 22. The pathologic report was hyperplasia of the thyroid.

She was completely relieved of her symptoms for five years and was seen next on Sept. 8, 1931, because of a recurrent nodule in the left side of the neck and vitiligo, which had recently appeared on the hands. Her basal metabolic rate was -18 per cent and she presented no signs of recurrent hyperthyroidism. She was advised to take 1 grain (0.065 Gm.) of thyroid extract (Parke Davis & Co.) daily. She returned in June 1932 and stated that shortly after her last visit to the clinic she had noticed dryness of the skin and brittleness of the nails, that her hair was falling out and that she was slightly drowsy most of the time. At the time of onset of these symptoms she had noted thickening of the skin on the lower surfaces of the legs and about the ankles. She also complained of some burning and itching of the lower portions of the legs.

On the lower third of each leg on the anterior and lateral surfaces there were pink, thickened edematous plaques. The follicles of the skin showed dimpling and produced a pigskin appearance of the surfaces of the lesions. These areas did not pit on pressure. The hair was dry and the nails were brittle. There was no edema of the feet or ankles. There was a subacute erythematous scaly dermatitis around the eyes which had been produced by a cream that she had used to remove wrinkles. At this time the basal metabolic rate was $+6$ per cent. A diagnosis of circumscribed myxedema of the skin and hypothyroidism was made. She was advised to continue with thyroid extract and to take tartaric acid, di-iodide.

Our next observation was made in November 1932. The patient had become nervous and overactive and had noticed dyspnea on exertion. She presented signs suggestive of a recurrence of hyperthyroidism. Her hair was dry and the nails were still brittle. The myxedematous plaques had enlarged and there was slight edema of the legs.

A biopsy was obtained from the right leg and showed that the histologic changes in the skin were limited to the dermis. The epidermis was normal except for some obliteration or flattening of the interpapillary pegs due to the changes in the corium. In the corium, with the exception of the papillary layer, there was marked separation of the collagenous stroma by a deposit of a mucinous substance. There were several small areas of perivascular lymphocytic infiltration throughout the corium.

Five months later the patient was even more nervous and excitable. The neck and upper portion of the chest were flushed and the skin over the body was moist. Her hands were unsteady but did not display a true hyperthyroid tremor. The patient had slight tachycardia but no exophthalmos. The nodule in the neck had enlarged considerably. The appearance of the patient was more suggestive of recurrent hyperthyroidism than it was at her previous consultation. The basal metabolic rate was $+14$ per cent. Compound solution of iodine was prescribed, and after she had been taking the iodine preparation for two months her general health had improved and the tachycardia had disappeared. She exhibited none of the signs of hyperthyroidism. However, the plaques on the legs remained unchanged, despite the general benefit derived from iodine therapy.

CASE 2—An unmarried woman aged 46, admitted to the clinic, July 22, 1924, stated that in 1917 she had become very nervous, had lost weight, and had suffered from dyspnea and tachycardia. Following a thyroidectomy, she had regained her health and had remained well until September 1923 when she had noticed a swelling in the region of the thyroid gland. She had become nervous, her pulse rate had increased and she had noticed that she tired easily. On admission there was a moderate nodular enlargement of the neck in the midline and in the region of the left lobe of the thyroid. The pulse rate varied from 90 to 120 per minute, and the tachycardia was not relieved with rest in bed. A diagnosis of recurrent adenoma of the thyroid with hyperthyroidism was made. Following the removal

of the recurrent nodule of the thyroid gland there was a complete alleviation of her symptoms. The pathologic report at that time was colloid adenoma of the thyroid.

The patient returned to the clinic in August 1931, complaining of persistent thickening of the skin on the lower portions of each leg. This first had appeared in 1929 as pink, thickened plaques in the pretibial areas. These lesions gradually increased in size until the anterior and lateral surfaces were involved. There was a moderate amount of itching and burning of these plaques and also an increase in the growth of the hair on the legs. Although her ankles and feet did not swell she thought that the legs seemed larger when she was on her feet for a long time. She had taken thyroid extract since the onset of this condition but had noticed no change in the skin on the legs. Her general health was good.

Except for the cutaneous changes, the patient presented no physical abnormalities. The skin over the body was normal. The lower two thirds of each leg was almost completely encircled by a pinkish, brownish yellow edematous skin which

Fig. 1 (case 2)—Diffuse plaque of circumscribed myxedema

did not pit on pressure. The myxedematous change was most marked on the anterior and lateral surfaces of the legs. The upper margins of these areas were poorly defined, while the margins just above the ankles were raised and sharply demarcated. The skin around the ankles was in folds but did not have the appearance of that on the lower portions of the legs. The skin on the feet was not edematous and was of normal texture. The dimpling at the follicles made the surface of the involved skin look like pigskin. There was an abnormal amount of coarse, black hair on both legs.

A biopsy from this area showed that the epidermis appeared practically normal except for a moderate amount of hyperkeratosis and some obliteration of the interpapillary pegs. There was edema of the papillary and subpapillary layers of the dermis. The collagenous fibers of the corium and subcutaneous tissue were fragmented, poorly stained and widely separated by a mucinous deposit. This change was less marked in the area around the pilosebaceous follicles. Throughout the corium and especially around the follicles there were small areas of perivascular lymphocytic infiltration. The small sheath of fibrous tissue surrounding the pilosebaceous follicles, which was to some degree free of the mucinous infiltration may have been

an important factor in the causation of the dimpling of the follicles in these myxedematous areas

The patient's basal metabolic rate was -18 per cent. Thyroid medication, even in sufficient amounts to produce systemic symptoms, failed to bring about any change in the condition of the skin on the legs.

CASE 3—A man, aged 53, admitted to the clinic, Dec. 6, 1927, complained chiefly of nervousness, loss of weight, fatigue and tachycardia, which had persisted for a year. He was thin and poorly nourished. The physical examination revealed that he had an enlarged nodular thyroid gland, a fine tremor of the fingers and a pulse rate of 105 per minute. The skin was flushed and moist.

Following a thyroidectomy his symptoms disappeared. Shortly after this operation he had several attacks of transitory auricular fibrillation. He returned at various times during the next five years for observation. Several determinations of the basal metabolic rate during this time varied between $+10$ and -18

per cent. The signs of hypothyroidism were relieved by thyroid extract.

In the spring of 1932 a red area appeared on the lower anterior surface of the left leg. Soon afterward a similar lesion developed on the right leg. These lesions were accompanied by a slight amount of itching. The original lesions had enlarged and appeared as irregular, raised, brownish-pink edematous plaques with a surface resembling pigskin. They did not pit on pressure.

The patient was next observed in July 1932 at which time he stated that for the past five months he had noticed a return of his former symptoms of fatigue, nervousness, tachycardia, perspiration and loss of weight. The basal metabolic rate at that time was $+10$ per cent. There was a recurrent nodule in the

Fig. 2 (case 4)—Tawny nodular plaque of localized myxedema

region of the left lobe of the thyroid gland. Dr. Crile was of the opinion that the symptoms were manifestations of an unstable, irritated sympathetic nervous system and that the recurrent hyperthyroidism was in a state of remission. A bilateral adrenal denervation was performed and the recurrent hyperplastic thyroid tissue was removed. Two months later the patient was feeling well, had gained weight and was free from his former symptoms, yet the myxedematous plaques remained unchanged. Six months later the basal metabolic rate was -11 per cent. The skin was dry and there was some edema around the eyes; the patient was advised to take thyroid extract.

CASE 4—A man, aged 52, admitted to the clinic Jan. 23, 1929, complained of nervousness, irritability, fatigue and tachycardia. These symptoms had been present for two years and were gradually increasing in severity. In the last year the thyroid had gradually enlarged and had recently produced a choking sensation and a feeling of fullness in the neck.

Physical examination revealed a diffuse enlargement of the thyroid gland, tremor of the fingers and a mild tachycardia. The diagnosis was adenomatous goiter with mild hyperthyroid-

ism. Thyroidectomy was performed, February 12. A section of the thyroid showed diffuse hyperplasia with multiple adenomas.

In October 1931 the patient returned, complaining of drowsiness and of soreness of the muscles. He said that he became tired easily and had noticed that his memory was poor. Six months later he was still complaining that the drowsiness and listlessness were persisting, and he complained also of an eruption, which had appeared on the anterior surfaces of both legs in January 1932 as small, red, slightly itchy areas in the pretibial areas. The lesions had gradually enlarged.

On the anterior surface of the lower third of each leg there was a raised, irregular, palm-sized, brownish red, edematous plaque. The thickness of the lesions varied, giving them a slightly nodular appearance. The surface of the lesions was glossy and when the skin was stretched, dimpling of the follicles occurred. There were several small globular, translucent papules on the surface of each lesion. The involved skin was more erythematous than in other cases in this series. Pitting could not be produced by pressure. A biopsy from one of the lesions showed changes identical with those observed in cases 1 and 2.

There was no edema of the legs or around the eyes. The skin and hair were normal. The basal metabolic rate was -12 per cent. The patient was instructed to take 3 grains (0.2 Gm.) of thyroid extract daily (Armour's). One year later his basal metabolic rate was -22 per cent. He had received no benefit from thyroid medication. The plaques on the legs had not changed. He was advised to take $\frac{1}{60}$ grain (0.0008 Gm.) of thyroxine daily. He was seen again June 14, 1934. The plaques had materially diminished in size, leaving a slightly pigmented atrophic scarring.

CASE 5—A man, aged 45, admitted to the clinic, Feb. 9, 1934, complained of nervousness, weakness, tachycardia, dyspnea, loss of weight and hyperhidrosis of a year's duration. In 1930 he had had a thyroidectomy for hyperthyroidism. He improved but failed to regain his strength. Two weeks following his operation, edematous plaques had developed on the lower portion of each leg. These were not accompanied by any subjective symptoms.

The patient was thin and weak. The skin was flushed and moist and the pulse rate was 130 per minute. Exophthalmos was present and was most marked on the right side. There was a fine digital tremor. In the region of the thyroid to the left of the trachea underlying the operative scar, there was a firm mass about 3 by 5 cm. The basal metabolic rate was $+55$ per cent.

On the lateral and anterior surfaces of the lower two thirds of each leg there were large, raised, brownish pink edematous plaques. The lesions were elastic and did not pit on pressure. The surfaces of the plaques were uneven, producing a nodular appearance. In this respect the lesions were similar to those seen in case 4. Dimpling of the follicles was apparent only when the plaques were stretched. When a biopsy was taken from one of the myxedematous plaques, some difficulty was experienced in closing the incision as the skin was so friable that the stitches would not hold. A great deal of mucinous material exuded from the cut surfaces of the skin. The histologic changes were similar in every detail to those observed in cases 1 and 2, but the deposit of mucin was more marked than in any of the four cases in which we were able to obtain a biopsy.

A second thyroidectomy was performed on this patient, and he was relieved of his symptoms and gained weight rapidly. When he was last seen, June 14, 1934, the myxedematous plaque on the left leg was approximately one-half its original size.

CASE 6—A lawyer, aged 27, admitted to the clinic, May 12, 1934, complained of hyperhidrosis, loss of weight, tachycardia, dyspnea and nervousness of about six months' duration. He had had measles, mumps and chickenpox in early childhood. In 1926 diabetes mellitus had appeared, following an attack of influenza and in January 1933 symptoms of hyperthyroidism were evident. At first roentgen therapy was tried but without relief of his symptoms. Following a thyroidectomy in April 1933 the patient gained weight and remained well until November 1934 when he noticed a return of his former symptoms.

Again roentgen therapy to the thyroid region failed to be beneficial, and some exophthalmos developed.

At the time of the recurrence of the hyperthyroidism in November 1934 he noticed a pink itchy spot on the lower portion of the left leg. In a few days a similar lesion appeared on the right leg. When these areas were scratched they became erythematous. These lesions gradually enlarged until the lower third of the anterior and lateral surfaces of each leg was involved. At times the itching had been troublesome.

The patient was well developed and well nourished. His skin was moist and there was hyperhidrosis of the palms. There was a definite bilateral exophthalmos. The pulse was 104 per minute and irregular. The irregularity was due to premature ventricular systoles with frequent periods of bigeminal rhythm. There was no palpable thyroid tissue. There was no evidence of peripheral edema but there had been some edema of the legs during the patient's original attack of hyperthyroidism. The basal metabolic rate was +22 per cent. The fasting blood sugar was 282 mg per hundred cubic centimeters, urea 51 mg, and nonprotein nitrogen 28 mg. The blood proteins were 65 mg with albumin 32 mg and globulin 33 mg. The blood Wassermann and Kahn tests were negative.

On each leg in the pretibial regions there were large poorly defined, brownish yellow to pinkish, edematous nodular plaques which did not pit on pressure. The lesions had a waxy appearance, and dimpling of the follicles made them resemble pigskin. A biopsy from the plaque on the left leg showed histologic changes identical with those observed in the other cases.

COMMENT

Pillsbury and Stokes⁴ divided the cases of circumscribed myxedema of the skin into two groups: (1) the nodular type with lesions involving the face, arms, back, and scrotum; and (2) those with myxedematous plaques limited to the pretibial areas. The latter type is invariably associated with hyperthyroidism. These observers state that the only consistent point of similarity between the two groups is the histologic change.

The cases reported here fall into the second classification. The cutaneous lesions are symmetrical, irregular, raised, slightly erythematous or brownish yellow edematous plaques involving the skin in the pretibial areas. In most instances dimpling of the follicles gives the surface of the lesion an appearance resembling pigskin. In two of our cases small dome-shaped, translucent papules were present on the surfaces of the larger plaques. The myxedematous changes in the skin usually develop after the manifestations of initial or recurrent hyperthyroidism have become apparent, but in one of O'Leary's cases the cutaneous lesions appeared first. Lesions may develop during the active manifestations of thyroid intoxication or at varying periods after the patient has been relieved by thyroidectomy. Following thyroidectomy signs of hypothyroidism or mild generalized myxedema of a more or less transitory nature may precede or accompany the development of the myxedematous plaques on the legs. The administration of thyroid extract in most instances causes an improvement or a complete disappearance of these symptoms without producing any change in the localized lesions.

The skin and hair may be dry and the nails become brittle. However, the hands and feet are not swollen and the edema about the eyes and face and the subcutaneous edema or the cushion-like accumulation of fat in the supraclavicular regions, which develop in a marked case of generalized myxedema, do not form a part of the clinical picture of circumscribed myxedema of the skin. The patient may or may not complain of itching and burning of the involved skin. Five of our six patients complained of these symptoms.

The histologic changes are essentially limited to the corium. The collagenous fibrous tissue is fragmented

and widely separated by a mucinous deposit or degeneration. This change occurs also in the subcutaneous tissue and to a slight extent in the papillary layer. There is a small zone of fibrous tissue around the pilosebaceous follicles that is relatively uninvolved. Because of this the follicles become at least partially fixed, thereby becoming a factor in causing dimpling at their orifices. There is a moderate amount of lymphocytic perivascular infiltration throughout the corium, being especially marked around the pilosebaceous follicles. Several authors have commented on the occurrence of large numbers of stellate cells in the corium. Pillsbury and Stokes speak of them as immature connective tissue cells.

The etiology and mechanism of production of circumscribed myxedema of the skin is unknown. O'Leary, Ingram, and others have mentioned the passive edema

Fig. 3 (case 5).—Section showing marked deposition of mucin with fragmentation of fibrinous collagenous tissue. Involvement of the fibrinous tissue immediately adjacent to the follicle is lacking.

of the extremities that occurs in cases of hyperthyroidism with auricular fibrillation and cardiac embarrassment as a probable etiologic factor. A disturbed function of other glands of the endocrine system is frequently observed in cases with thyroid dysfunction and has been observed in reported cases of circumscribed myxedema, but conclusions cannot be drawn from these observations. Many cases of hyperthyroidism present edema of the legs as well as evidence of secondary endocrine dysfunction, but in few of them does localized myxedema develop.

In an attempt to explain the constant involvement of the lower legs in the plaque type of circumscribed myxedema, Pillsbury and Stokes have suggested that the circulatory stasis of the legs commonly observed in hyperthyroidism has in some way changed the usually reversible condition of myxedema into an irreversible process. They therefore argue that, in such instances, the administration of thyroid extract aggra-

vates the circulatory embarrassment, which originally was a factor in the production of the lesions. Our greatest barrier to a solution of this problem is our meager knowledge of the physiologic chemistry of normal and myxedematous skin.

In a discussion of the case reported by Lord and Morrison, Stryker suggested that trauma might be a factor in determining the location of the lesions in the pretibial regions. Although the legs are frequently subjected to trauma, there is nothing in the reports that we have seen or in the cases we have observed to support this opinion.

Circumscribed myxedema of the plaque type must be differentiated from lymphedema and scleroderma. There is considerable similarity in the clinical appearance of these three conditions. The history and the progress of each case is of importance, yet it may be necessary to obtain a biopsy before a correct diagnosis can be made. In scleroderma and lymphedema there is more proliferation of the connective tissue and more inflammatory reaction in the corium. In the latter condition the dilated lymph spaces can be made out. The marked mucinous infiltration that occurs in myxedema is an important finding in the differential diagnosis. Mucin has been observed in sections of scleroderma, but in very small amounts. It is possible that leprosy might roughly simulate this type of myxedema, but careful bacteriologic and histologic investigations should serve to establish the diagnosis.

Our present treatment of circumscribed myxedema of the plaque type is unsatisfactory. Thyroid extract, iodine and products of other endocrine glands have not been beneficial. In some cases the condition has cleared up spontaneously. In the first case reported by Pillsbury and Stokes the administration of iodine aggravated the symptoms of hypothyroidism, while a moderately excessive dose of thyroid extract produced toxic symptoms. A somewhat similar response to iodine has been reported by Haines.⁹ He described an instance of hyperthyroidism in which hypothyroidism developed following a partial thyroidectomy. Thyroid extract was administered but produced a recurrent hyperthyroidism, which could be controlled by iodine. Iodine alone produced myxedema, while thyroid extract caused a return of the symptoms of hyperthyroidism, however, when iodine and thyroid extract were administered together the patient improved. Haines concluded that in this instance there was not a hypersecretion but an altered secretion of the thyroid hormone. The agent that is probably responsible for the production of hyperthyroidism was being secreted without an excess of normal secretion, which usually occurs in this disease. A similar response to treatment of the general symptoms was obtained in the first case in this series.

SUMMARY

The six cases that form the basis of this report are examples of circumscribed myxedema of the plaque type. In all instances the myxedematous plaques developed after the initial attack of hyperthyroidism. In the third, fifth and six cases the lesions appeared simultaneously with recurrent hyperthyroidism, while in the first case the lesions were accompanied by symptoms of transitory hypothyroidism prior to the development of recurrent hyperthyroidism. In the second case the plaques developed six years after a second thyroidec-

tomy, while in the fourth case the plaques of myxedema were associated with definite signs of hypothyroidism, which appeared two years following thyroidectomy. In four cases in which we have been able to make observations for several months, the plaques have remained unchanged in two instances, and in the other two the lesions have gradually become smaller.

Transitory auricular fibrillation developed following thyroidectomy in the third case. The marked edema of the legs such as is frequently observed in hyperthyroidism was not present in any of these cases.

The lesions of circumscribed myxedema of the skin associated with hyperthyroidism may appear as nodules or large plaques. They invariably involve the skin in the pretibial regions. Case 2 is an example of the distribution in large plaques. The lesions in the remaining five cases in this series presented the more common nodules or smaller plaques.

In all probability, circumscribed myxedema of the skin associated with hyperthyroidism is not as uncommon as the reports in the literature would indicate. Since this condition gives very little discomfort, the patient and the physician give very little consideration to these cutaneous lesions. This is especially true if the physician is not particularly interested in dermatology.

Clinical Notes, Suggestions and New Instruments

GAILLARDIA DERMATITIS

A HITHERTO UNREPORTED PLANT CAUSE OF DERMATITIS VENERATA
ADOLPH ROSTENBERG JR. M.D. AND CHARLES KENN GOOD M.D.
NEW YORK

Gaillardia is a member (tribe) of the family Compositae. There are at least twenty eight species occurring in this country, the majority of these occur naturally but many are under cultivation as well. The territorial range in the United States is from the Atlantic to the Pacific and from Canada to Mexico. The members of this tribe flower anywhere from March until the late fall, dependent mainly on the climate of the particular locality. Those growing in this region bloom from June until the first frost.¹ Because of the ubiquity of this plant, because we cannot find any reference in the literature to sensitizations produced by it and because we believe it to be a not uncommon irritant we deem it worth while to draw the attention of the medical profession to this plant as a possible cause of certain cases of dermatitis venenata.²

REPORT OF CASES

CASE 1³—S. B., a white man, aged 32, a florist, first developed a scaling eczema of the hands in May 1929. This became worse during the summer and gradually cleared up after the frost. In 1930, 1931 and 1932 he suffered from a repetition of the same process. He stated, however, that at one time during the height of the eruption when it was so bad that it necessitated the discontinuance of his work, the eruption temporarily cleared up only to relapse on the resumption of his occupation.

From the Dermatologic Service of the New York Post Graduate Medical School and Hospital of Columbia University. Dr. George Miller MacKee, director, service of Dr. Fred Wise.

1 Personal communication to the authors from Dr. E. D. Merrill, director of the New York Botanical Garden.

2 Touton in his exhaustive review on plant dermatitides does not mention Gaillardia although the plant is cultivated extensively in Germany. Jadassohn, J. Handbuch der Haut und Geschlechtskrankheiten, Berlin Julius Springer, 4 part 1 p. 487, 1932. Weber in his review of cutaneous irritants does not mention it (Arch. Dermat. & Syph. 21: 761 [May 1930]). In a circular put out by the Lederle Laboratories, Inc., a case of dermatitis from Gaillardia is mentioned but this case has not been reported and is included in this report (case 1).

3 A case of Dr. K. L. Druct of Salina, Kan., through whose courtesy we are reporting it.

⁹ Haines, S. F. Exophthalmic Goiter and Myxedema. Report of a Case. Endocrinology 12: 55-58 (Jan. Feb.) 1928.

In 1932 he was seen for the first time by Dr Druet, who applied patch tests with various plants and found him to give a four plus reaction to gaillardia. An oil extract of the plant was made by Dr A F Coca to which the patient was found to be strongly hypersensitive by patch test. He was given six injections of 0.5 cc each of the oil extract intramuscularly with a complete subsidence of symptoms and during 1933 and 1934 he has been able to handle gaillardia without gloves and without symptoms.

CASE 2—R C, a white housewife, aged 38 seen July 10 1934 had moderate swelling and edema of both eyelids. Similar lesions were present over the anterior surfaces of both arms and of both legs. The patient had had a similar eruption for the past three years. It would appear in the spring and gradually disappear in the fall. She definitely stated that country air made her worse; that is, she was better when she stayed in the city (she lived in a Long Island suburb) and that when she went for a drive in the country her eyes would begin to smart and to itch. She stated that she did not use any hair lotions or other applications to the head or the face except ordinary soaps and cosmetics. Therefore, because of the localization, because of the seasonal incidence and because of the lack of other probable causes, patch tests were done with twenty-four plants, which she brought in to us. She gave a weakly positive reaction to several of these (unidentified weeds) but she gave a four plus reaction to gaillardia leaf. This reaction consisted of marked vesiculation on an erythematous base and this site remained inflamed for at least twelve days, whereas the other locations could not be recognized after from forty-eight to seventy-two hours. When informed of the result of the patch tests she volunteered the information that three years before, when the eruption began, gaillardia had been planted and that this year the eruption had started after she had picked gaillardia. The tests with gaillardia were repeated several times with the same results. She also gave a four plus reaction to the gaillardia allergenic oil (Lederle). Scratch tests with macerated parts of the gaillardia plant were dubiously positive. Passive transfer experiments according to the method of Prausnitz and Küstner were done with negative results. It was decided to attempt desensitization⁴ and accordingly she was given two doses of 0.5 cc each of the gaillardia allergenic oil (Lederle) intramuscularly at an interval of two days. Her skin condition improved and she could go about in her garden without experiencing any untoward symptoms.

CASE 3—This case is reported in less detail as the diagnosis is not clear cut and as the chief interest of the case is the patient's reaction to various plants on the application of these as patch tests. A white man, aged 54, a native of Shrewsbury, Mass., developed itching, burning and swelling of the eyelids in 1930 as well as scaling, itching, lichenified lesions on each side of the neck. These lesions had persisted intermittently to date. On the application of various substances as patch tests he gave a four plus reaction to ragweed oil, pyrethrum, gaillardia oil and doubtfully positive reactions to chrysanthemum and dandelion leaves.

COMMENT

While gaillardia has an important significance as the etiologic agent in certain cases of dermatitis venenata, we believe that it possibly has a wider role than would at first sight seem apparent. As stated, gaillardia belongs to the large botanic family named Compositae, to which chrysanthemum (from which pyrethrum is obtained), ragweed, Helium (sneezeweed), Taraxacum and Krigia (dandelions), Tanacetum (tansy), Parthenium (Mexican bird seed weed), burweed, marsh elder (*Iva xanthifolia*) and many others belong. Those named have been selected, as they occur plentifully in this country and well substantiated cases of dermatitis venenata have resulted from contact with each of them.⁵ The chemical nature of the irritant in certain ones of these is unknown but it is known to be an oil in the cases of ragweed⁶ and the

Helium⁷ and believed to be in the case of chrysanthemum.⁸ From the nature of the extract of gaillardia and Tanacetum, it would also appear likely that the specific irritant is an oil. Recently Feinberg⁹ has stressed the relationship between ragweed and pyrethrum allergy, particularly in respect to the protein fractions, and Brunsting and Anderson¹⁰ have discussed the problem in regard to the dermatitis inducing fraction. We believe it is possible that there is an identical oleoresinous irritant or that there are common oleoresinous irritants in the members of this plant family and that there is a positive correlation between the similarity of the chemical formula of the irritant and the closeness of the botanic kinship and also between the presence of identical chemical compounds and botanic relatedness. In other words, if all the members of the Compositae were arranged in a linear series, the mathematical chances of an individual who is sensitive to one member being sensitive to any other members would vary directly with the respective proximities of these in the series to the original plant to which he was found to be sensitive. Also the total number of sensitivities that any individual may present on testing with the various members of the Compositae will vary (other factors being equal, i. e., the total number of different tests in particular) with the closeness of the botanic relationships of the plants used as the test substances. There also seems to be evidence for a similar phenomenon within other botanic groups, as Rhus and Primula. This hypothesis, if substantiated, would be of extreme practical importance, as in a sufferer from any given plant dermatitis it would be necessary to be acquainted with the botanic relations of that plant and warn the individual against these. We have had the opportunity to test this hypothesis in only one of our cases and here it seemed to be true (case 3). Much work remains to be done in this field, particularly along the lines of isolating the irritant principles of various plants and establishing their chemical identity. On the clinical side, patch tests must be done with the botanic kin of various plants in order to determine whether or not there is a common cutaneous hypersensitivity to the members of any one botanic family, as we believe.

A SUCTION CURET APPARATUS FOR ENDOMETRIAL BIOPSY

EMIL NOVAK, M.D., BALTIMORE

Endometrial biopsy is now widely employed to secure portions of the uterine mucosa for microscopic study without subjecting the patient to anesthesia. For this purpose various instruments have been devised, based on the employment of suction, or suction combined with curettage (Klingler and Burch, Rock). When an anesthetic is necessary, there would be no point to selecting this procedure in preference to the customary dilation and curettage. The latter operation is also to be preferred when very thorough curettage is indicated, as when early adenocarcinoma is suspected. In other cases it is necessary only to secure smaller amounts of endometrium, as in the differentiation of the physiologic responses of the mucosa to one type or another of hormone stimulation. In this respect the endometrium is the registering board of ovarian endocrine activity, and its microscopic study often yields much more useful information than blood or urine hormone studies.

The endometrial suction-curet apparatus herein pictured was devised primarily for the so-called ovulation test, i. e., to determine whether or not a patient is ovulating. Its chief application is in cases of sterility in which no other cause can be determined when, for example, the husband is normal, the woman is menstruating more or less regularly, her tubes have been shown to be patent, and no metabolic, constitutional or endocrine abnormality seems to be present. In at least some of these the sterility is due to the fact that ovulation is not

occurring, for the occasional occurrence of nonovulatory menstruation has been abundantly demonstrated (Tietze, Anspach and Hoffman, Novak, and others)

To determine this point, it is necessary only to secure a small amount of endometrium just before an expected period. If the woman has ovulated, a corpus luteum has been formed, progesterin has been produced, and the endometrium is seen to show the typical secretory changes that only progesterin can evoke. If these changes are absent, i. e. if the endometrium shows only one type or other of proliferative but nonsecretory

Fig 1—Diagram of cannula and its connection with the bottle that receives the aspirated curettings. The tube at the left is connected with the motor suction pump. The tubing must be rigid as a flaccid tube would be collapsed by the strong negative pressure. As particles of tissue may adhere to the walls of the tubing the latter should be washed by sucking a formaldehyde solution, cold water or citrate solution through the open end of the cannula into the bottle after the operation. The cannulas either straight or curved may be obtained from the Murray Baumgartner Surgical Instrument Company, Baltimore. The curved type is the better for general use.

reaction, it may be safely concluded that ovulation has not occurred.

There is, of course, no claim as to originality in the principle of this apparatus, for the suction idea has been long employed by many gynecologists. I believe, however, that the electric motor suction which I employ is much more likely to yield satisfactory tissue than is suction by syringes. Indeed it is usually possible to curet a uterus very thoroughly by this method, without anesthesia and without noteworthy discomfort to the patient. When the technic fails to yield much tissue, a checkup with curettage under gas anesthesia has given the same result. As the particles of aspirated mucosa may at times adhere to the inner wall of the tubing, it is important to rinse the latter by sucking cold water or a citrate solution through the apparatus at the conclusion of the curettage. Either of these liquids seems preferable to a formaldehyde solution as the latter appears to shrink the particles and cause them to stick more closely to the tubing. The latter should be of a very rigid type, so that it will not collapse when the negative pressure is applied.

The cannula used is about the size of that employed in the Rubin tubal insufflation test. Either a straight or a curved tube can be employed, but the latter is the more generally useful.

Fig 2—Detail of the serrated fenestrum of the cannula. At the proximal end of the latter is a flattened disk to indicate the direction of the serrated edge.

The upper and lateral margins of the oval fenestrum near the tip are sharply serrated. The small diameter of the cannula permits of its introduction into the cervical canal, without dilation of the latter in the great majority of women, so that the method can be used as an office procedure. It is scarcely necessary, however, to stress the importance of careful aseptic technic. The suction is made by the ordinary electric suction machine found in all operating rooms, the curettings being drawn into a bottle as shown in figure 1. The only publication in which the electric suction technic is recommended for endometrial biopsy is so far as I know, the recent one of Bela Lorincz¹ of Hungary (1934). In

this the entire dependence is on aspiration, the cannula not being designed for simultaneous curettage.

Other uses for this technic will suggest themselves. For example, it is often easy to obtain abundant tissue for confirmation of the diagnosis in cases of adenocarcinoma of the uterus, or of hyperplasia of the endometrium. The method should be of value also in the study of the endometrium in cases of endocrinopathic amenorrhea, for comparatively little is known as yet as to the histologic pictures which may occur and which may aid in interpreting the causative endocrinopathies.

Finally, by the use of this simple technic, it may be possible to obtain fertilized ova in very early stages, even before implantation. By instructing patients as to the performance of coitus on selected dates in relation to the usual ovulation phase, and carrying out suction-curettage at appropriate times thereafter, there is little doubt that some one will sooner or later secure fertilized eggs at much earlier stages than the nine to eleven day old Miller ovum. Such studies presuppose a correlation between the gynecologist and the embryologist, but the method promises a great deal in this direction, in the opinion of Dr. George L. Streeter, the director of the Carnegie Institute of Embryology, whose valuable cooperation I have had. In the development of this useful little apparatus I have been much indebted for helpful suggestions to Drs. A. H. Crowther and R. H. Allison, the former and present residents at Bon Secours Hospital.

Special Article

GLANDULAR PHYSIOLOGY AND THERAPY

THE PHYSIOLOGY OF ESTROGENIC PRINCIPLES

EDGAR ALLEN, PH.D.

NEW HAVEN, CONN.

NOTE.—This article and the articles in the previous issues of THE JOURNAL are part of a series published under the auspices of the Council on Pharmacy and Chemistry. Other articles will appear in succeeding issues. When completed the series will be published in book form.—Ed.

The term "estrus," as used by Heape, designated the restricted period of mating activity of female mammals.¹ The outstanding criterion of estrus was the female's intense sex urge or drive. Since sexual activity in women and other female primates is not restricted to such brief intense periods, the term has not been used in connection with the menstrual cycle.

Recent experimental work with ovarian hormones has emphasized another aspect of estrus, namely, the rapid growth of the accessory genital organs, which ushers in the estrous period proper. This growth was first induced experimentally by the ovarian follicular hormone. This hormone is therefore primarily a growth hormone, its action affecting especially the female genital tract and mammary glands. The wall of the vagina of rodents, because of its structure and

From the Department of Anatomy, Yale University School of Medicine.

The writer wishes to acknowledge the assistance of Dr. William U. Gardner, Dr. Warren O. Nelson, Dr. Jack M. Curtis, Mr. A. W. Diddle, and Mr. T. H. Burford in the preparation of this paper. It is intended to stress some of the more important well established reactions to estrogenic substances rather than to go extensively into detail. For the reader interested in greater detail and extensive citations to the literature, several reviews are cited under reference 3.

¹ Marshall F. H. A. The Physiology of Reproduction. London 1922.

¹ Lorincz, Bela. Die Anwendung des Elektroaspirators in der Frauenheilkunde. München. med. Wchenschr. 81: 215-217 (Feb. 9) 1934.

location, is the best indicator of this experimentally induced growth.² Recent reviews may be found in the literature.³

With this indicator as a quantitative biologic unit, exploration of possible sources of active material has revealed a wide occurrence not only in various reproductive tissues of animals but also in plants and even in minerals.⁴ The collective terms "estrogenic principles or substances," including anything that will induce growth in vaginal epithelium have been adopted. At first these terms were limited to the reaction in ovariectomized animals, and the injected substances were required to replace ovarian endocrine function in this respect. Later they were extended to include pubertal effects in normal immature animals such as those produced by the anterior pituitary gonad stimulating hormone, for the vaginal reaction is similar although the ovaries are apparently necessary intermediaries for anterior pituitary effects. Also when theelin was differentiated from theelin, greater potency was described for it in immature normal animals than in ovariectomized adults.⁵ Similarly substances that activate otherwise resting ovaries in animals out of breeding season have also been included.⁶ A distinction should be clearly drawn, however, in the use of the term "estrogenic" between substitution effects for ovaries and for anterior pituitary.

Clinical interest in the subject has been intensified by reports that certain substances which produce carcinoma and are somewhat similar chemically to estrogenic hormones may also produce estrous changes.⁷ Since both reactions are fundamentally growth phenomena involving epithelial tissues primarily, the logic of the possibilities involved suggests further experimental exploration. The interest of investigators of nutrition has been aroused by reports that large doses of one of the vitamins may have an estrogenic action⁸ and that certain forms of inanition, such as diet low in specific proteins, may prevent estrous growth as effectively as does ovariectomy.⁹

In evaluating these reports, emphasis should be placed on the change of meaning the terms "estrus" and "estrogenic principles" now refer more to growth of genital tissues than to sexual receptivity of female mammals. The terms still have little logical application to the menstrual cycle. Further reference is made to this aspect of the question in another section of this series, "Menstruation."

There are other very important aspects of estrus, definite reactions of organs, which should be included

under a broad definition of estrogenic activity and which have not been tested thoroughly in connection with reports of estrogenic properties for some of these substances. These reactions can best be described as induced in ovariectomized animals by injections of the estrogenic hormone theelin.

Certain secondary sex characters in the female depend definitely on the presence of estrogenic substance. Among these may be listed plumage changes in certain birds,¹⁰ the extensive sexual swellings of the chimpanzee and baboon,¹¹ and the reddening and swelling of the "sexual skin" of some of the monkeys.¹² The feather reactions write a time record of the hormone concentration of the blood during feather growth, these serve as indicators of very small amounts of hormone, represented by color changes in restricted band of individual feathers.¹⁰ The variation of hormone thresholds for various effects has been established.¹³ The "sexual skin" changes are due to definite local vascular reactions and transformation of adjacent connective tissue.¹⁴ These reactions have been produced experimentally by replacement of ovarian endocrine function by injections of theelin.¹²

The vaginal growth reaction which has already been described as the most practicable unit for biologic standardization of estrogenic substances, is truly remarkable.¹⁵ In three days or less in either rats or mice a new vaginal epithelium is grown under the action of this hormone. This may mean the growth and differentiation of from twelve to twenty layers of stratified epithelial cells. The extent of this growth can be accurately followed by identification of the types of cells present in smears of vaginal contents. The disappearance of leukocytes that occur in the control smears of the ovariectomized animal and the appearance of cornified epithelial cells establish the completion of the growth phase.

The uterine reaction that parallels the vaginal growth in these rodents is equally striking.¹⁶ Large numbers of mitotic figures are present in the endometrium. Secretion of a serous fluid which is retained in the uterus distends it extremely and renders it translucent.^{16a} In addition, both amplitude and rate of uterine contractions are controlled in part by this hormone.^{16a} Estrogenic material will not, however, produce the pseudopregnant or progestational characteristics of the uterus. By injections of large doses over long intervals of time, it has been possible to induce certain types of abnormal endometrium.¹⁷

By ocular implants in rabbits it has been shown that follicular hormone has a vasodilator effect on the capillaries of the endometrium.¹⁸ In the ovariectomized animal, vasoconstriction accompanies castrate atrophy. Injections of theelin are followed by vasodilatation. This phase of the subject will be discussed further in the section on menstruation.

There is some evidence that secretion of certain cells in the epithelium of the uterine tubes is dependent on ovarian hormone action,¹⁹ that the contraction of the tubal musculature is regulated in part by it,²⁰ and that development of ciliated cells depends on this hormone.²¹

Estrogenic substances have no stimulating effects on the ovaries. Long continued injections of large amounts may even retard the development of ovaries of immature animals.²² This is in accord with the general principle that hormones do not stimulate the specific glands which secrete them.

The growth of the mammary glands is primarily dependent on the estrogenic hormones.²³ The primary ducts of the rudimentary mammary glands of males have been found to respond to both theelin and theelol.²⁴ At the present time the guinea-pig is the only species extensively investigated in which a complete growth of the mammary glands (both ducts and alveoli) may be induced by theelin. The simultaneous action of theelin and progesterin has been found necessary to produce complete mammary growth in other mammals so far studied.²⁵ Theelin also repairs the mammary glands of the ovariectomized monkey following castrate atrophy,¹² and induces some mammary growth in ovariectomized immature monkeys²⁶ and in male monkeys.²⁷

In addition to acting as a stimulant of the mammary parenchyma theelin induces growth in the epithelium covering the nipple.¹² The nipple growth of male guinea pigs has long been used as an index of successful ovarian grafts.²⁸ Theelin has been observed to produce a marked nipple growth in male guinea-pigs.²⁹ Though theelin may also have a definite reaction on the connective tissue stroma of the mammary glands, these effects have not been adequately studied.

Lacassagne has observed mammary cancer in male mice after their mammary glands had been developed

by treatment with estrogenic substance.³⁰ A development of small localized lobules of alveoli in addition to the ducts has been observed in the mammary glands of male mice of an inbred strain following injections of theelin over a long period.³¹ The latter investigation indicates that localized areas of the experimentally grown mammary ducts may be more sensitive to stimulation with theelin.

The reactions of the uterus and mammary glands so far described are those of the first half of the estrous cycle and the postmenstrual phase of the menstrual cycle. As one of the important actions of estrogenic substance, it should be emphasized that these reactions are necessary before action of the corpus luteum hormones progesterin and relaxin is possible.³² Mention should be made of the fact the large doses of estrogenic substance may override the effects of progesterin³³ and that progesterin can inhibit the effects of estrogenic substance.³⁴

In further comment on the growth reaction of genital tissues to estrogenic substances, it should be noted that these tissues in different animals have greatly different growth rates. For instance, it takes much longer to obtain growth in the vaginal epithelium in the monkey than it does in the rat or mouse.

The sexual drive of mating instincts is at least partly dependent on ovarian follicular hormone.³⁵ There is considerable experimental evidence to show that this substance is a major factor in determining this aspect of estrus.³⁶ In addition to the drive of sex urge, there seems to be related to it in some animals a period of increased spontaneous activity.³⁷ In the female rat this has been measured by voluntary running in a rotary cage. The ovariectomized animal has no such periods of spontaneous activity. These periods can be induced again by ovarian transplants³⁸ and have recently been demonstrated following injections of estrogenic hormone.³⁹ Nervous tissues may react to different levels of estrogenic substance. A change in certain reflex actions during periods of rise in hormone level has been reported.⁴⁰ When measurable changes can be demonstrated in reflex actions, one is prepared for

reports that psychic states may be influenced by the blood level of this hormone.⁴¹ There is considerable variation in the threshold of hormone concentration required for reactions in different organs. The estrous reaction in the uterus requires much more hormone than that in the vagina,⁴² while mating reactions require still greater amounts.⁴³

The possible effect of estrogenic substances on the basal metabolism has been studied by many investigators. No clear cut effect has yet been demonstrated. This phase of the problem is discussed more fully in other papers of this series dealing with the interrelations of pituitary, gonads and thyroid.

Immature female rats and mice, both normal and ovariectomized, can be brought to a sexually mature condition in four or five days by the right concentration of estrogenic substance.⁴⁴ From these experiments it is reasonable to suppose that it is the more gradual secretion of this material that normally induces puberty.

In the pocket gopher estrogenic substance definitely causes a resorption of the symphysis pubis, thus enlarging the birth canal. This occurs in the female before the first ovulation and has been shown to be definitely due to theelin.⁴⁵ Enlargement of the birth canal of the guinea-pig at parturition is effected by relaxation of the pelvic ligaments under the successive action of theelin and a corpus luteum hormone, relaxation.⁴⁶

It is possible to ovariectomize the pregnant guinea-pig half way through gestation without causing abortion if there are not more than two fetuses in utero.⁴⁷ The pelvic ligaments relax at parturition in such animals. This introduces the possibility that both theelin and relaxation may be produced in the pregnant guinea-pig by the placenta. The ovaries can also be removed from the pregnant mare without upsetting the endocrine balance.⁴⁸ It has been demonstrated that the ovaries can be removed after the middle of gestation without interfering with growth of the mammary glands and their function after parturition.⁴⁹

During pregnancy in some mammals estrogenic substances play a very important part which is little understood at present. As pregnancy progresses, large amounts can be demonstrated in the circulating blood⁴⁸ and in the urine.⁵⁰ The corpus luteum during early pregnancy,⁵⁰ the placenta in increasing amounts as it grows with the progress of gestation,⁵¹ the amniotic

fluid,⁵² the umbilical cord and the fetal blood from the cut end of the cord⁵³ all show a high estrogenic content. In some animals (cat and dog) there is not enough present to give positive tests. That the placenta may take over the function of secreting this material during pregnancy in women⁵⁴ and in mares⁴⁷ is indicated in several cases of ovariectomy during early pregnancy without diminution of hormone excretion.

There have been several studies of possible action of estrogenic material in producing abortion.⁵⁵ Injections of massive doses of the impure extracts have terminated pregnancies in rats and mice but these animals can tolerate much more of the purified preparations without terminating pregnancy.⁵⁶ It is difficult to credit such a function in the normal animal when the high content of estrogenic substance in the blood during pregnancy in women is so well established.

The urine as a source of estrogenic substances was first established in samples from pregnant women.⁴⁸ This provided a plentiful and inexpensive source of supply which greatly accelerated chemical work on purification of extracts. The excretion of estrogenic substance by the normal, menstruating, human female has been recognized since 1925,⁵⁷ but only recently have the daily variations of this excretion been studied and their significance appreciated. The curve of the hormone concentration in the urine shows two peaks during the normal menstrual cycle.⁵⁸ The first and smaller occurs at about the 10th to 19th day of the cycle and may be correlated with the time of maximum growth of the follicle, ovulation and early corpus luteum formation. A second period of increased excretion occurs about the 21st to 24th day of the cycle. This peak may correspond with some phase of activity of the most recent corpus luteum. Immediately after the peak is passed there is a precipitous drop in the excretion of estrogenic substance followed normally by the onset of menstruation. When the normal cycle is disturbed by pregnancy there is a gradual rise in the level of excretion of estrogenic substances starting the latter half of the second month⁵⁹ and continuing throughout the period of gestation. The maximum excretion is in the neighborhood of 3,000 rat units per liter. After parturition the level of excretion falls rapidly to normal in four or five days.

There remains much to be done in the study of estrogenic substances in relation to the maintenance of hormone concentration during replacement therapy. Injections of water soluble preparations made at daily intervals by no means approximate the normal secretion of this material. Considerable evidence exists that an

effective level of hormone concentration can be better maintained by the injection of hormone in oil or some other medium less rapidly absorbed than water.⁶⁰ The rapid retrogression of hormone effects on cessation of injections and the rapid drop in excretion of estrogenic substances after parturition indicate that there is little or no storage of the hormone in the body.⁴

The estrogenic hormones, particularly theelin, have been shown to exert a depressant action on anterior pituitary function. This was first demonstrated for the gonad-stimulating activity of the hypophysis.⁶¹ This phase of the activity of estrogenic hormones has been incorporated in a hypothesis of the existence of a reciprocal relationship between the anterior pituitary and the gonads.^{61a} The reaction to castration of the anterior pituitary components related to the gonads has been shown morphologically by the finding of changes in the basophils⁶² and physiologically by the increased content of gonad-stimulating hormone.⁶³ Estrogenic substance will prevent these changes in the castrate animal and will suppress the normal activity of the intact animal.⁶⁴ This action as a factor controlling anterior pituitary activity has been extended to the growth-promoting function⁶⁵ the lactogenic function^{66b} and the diabetogenic activity.⁶⁶

Several investigators have recently shown that growth of certain types of tumors is associated with disturbances in the available supply of estrogenic substance in the body. This change may be reflected particularly in abnormal structure and function of the genital organs. Instances in which this is an outstanding feature are those of precocious development in young girls and the reestablishment of menses in women past the menopause. In the latter cases granulosa cell tumors, which secrete large quantities of estrogenic substance have been found responsible for the sexual disturbances.⁶⁷ In women, cystic ovaries have been found associated consistently with uterine fibroids and hypertrophied endometria. The latter may be due to a hyperovarian condition.⁶⁸ This seems particularly significant since some of the carcinogenic substances may also have estrogenic activity.⁸

Ovarian hormones play such dominant roles in controlling growth and function of genital tissues that many investigators have attempted to produce atypical growths by excessive stimulation with hormones.⁶⁹ By removal of the ovaries from guinea-pigs and early in life from carefully inbred mice which normally develop a high incidence of spontaneous mammary tumors, the percentage of tumors produced has been markedly reduced.⁷⁰ Prolonged injections of estrogenic substance have produced atypical growths in the mammary rudiments of male mice from inbred strains which normally show a high incidence of spontaneous mammary tumors in the females but none in the males.¹

With growth of spontaneous mammary tumors in mice the estrous cycles become progressively longer and finally disappear. The ovaries in such animals are atrophic. Estrous reactions may be produced in the genital tract by injections of estrogenic substance and sometimes by the stimulation of pituitary implants.² In the former case the action is directly on the genital organs, in the latter, follicular growth is stimulated in the atrophic ovary.

Long continued injections of theelin have induced atypical growths of the epithelium of the uterine cervix in monkeys, these growths in some respects approach early cancerous conditions.⁷³ Further work is necessary to clarify the possible relation of ovarian hormones to atypical growths of genital tissues after long periods of dioestrus.

CONCLUSION

Emphasis should be placed on several fundamental points in the physiology of estrogenic substances.

First, as a major objective the fundamental endocrine mechanism of the estrous and menstrual cycles has been demonstrated. Active hormones have been isolated and their relation to one another partially worked out.

Second, incidental to the first point, the reaction of the rodent's vagina has provided a practicable test for the biologic standardization of therapeutic products, and these have now replaced the inert gland extracts previously in wide clinical use.

Third, the extension of the test to carcinogenic substances and to other substances of similar chemical structure from a wide range of sources is extremely important. In description of some of the carcinogenic and estrogenic substances, the time interval required may be considerably greater than that required for the growth phase of the estrous reaction to theelin. The reasons for variations in the time of reaction are not clear. It is not yet known whether some of the related substances included under the term "estrogenic" will produce more than the vaginal growth reaction. Few of them have been tested as to value in replacing other phenomena of estrus or menstrual phenomena in primates.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORTS HOWARD A. CARTER, Secretary

ANNUAL MEETING OF THE COUNCIL ON PHYSICAL THERAPY

The annual meeting of the Council on Physical Therapy was held at the headquarters office of the American Medical Association, Friday and Saturday, January 25 and 26. The Council has been actively engaged in its work for nine years.

Dr. Harry E. Mock, Chicago, was reelected chairman and Dr. Frederick J. Gacnsien, Milwaukee, vice chairman.

Some of the matters that came up for discussion were post-graduate and undergraduate instruction in physical therapy extension courses in physical therapy in the state and county medical societies, consideration of radium and radon compounds and of x-ray equipment, and investigation of orthopedic appliances, belts, shoes and posture appliances. Revision of the Handbook of Physical Therapy was discussed and the Council decided to prepare for distribution a booklet of accepted and nonaccepted devices.

In the matter of education, the Council adopted a revised plan whereby speakers may be made available to state and county medical societies. Details of this plan may be obtained by writing to the secretary of the Council. A group of consultants on education have been appointed by the Council to aid in the promotion of these extension educational courses throughout the country. The Council acknowledged the hearty cooperation of the consultants, namely, Drs. Disraeli Kobak, Chicago, A. J. Kotkis, St. Louis, Richard Kovacs, New York, and Franklin P. Lowry, Newton Mass. These physicians have worked faithfully in promoting physical therapy within their states and localities.

The Council voted thanks to the Committee on Standardization of Instruments and drugs of the Section on Ophthalmology of the American Medical Association for its splendid work in connection with the investigation of spectacle lenses and ophthalmologic devices.

In view of the undesirable use to which reprints of Council reports and articles were put the Council voted that reprints would not be issued to manufacturers.

Careful consideration was given to the subject of short wave diathermy. Since the results of the special investigations under the direction of the Council have not been published, it was felt best to withhold the acceptance of short wave machines until the results were available.

Grants in aid of research have been utilized to the utmost capacity. The Council was pleased to note that most of the recipients of these grants had published the results of their investigations.

ACCEPTANCE OF SHOES

The Council on Physical Therapy of the American Medical Association has been requested to consider for acceptance or rejection shoes designed to prevent and correct foot disabilities. The Council is prepared to give such consideration because it believes that at the present time unwarranted and misleading therapeutic claims are being made for certain makes of shoes.

Manufacturers of ready-made shoes deserve much credit for the great diversity of shapes and sizes of shoes which they have made available to the public. However, it must be remembered that human feet vary in type with the general body build, and that the highness or lowness of the arch with the foot at rest is an unreliable criterion by which the functional efficiency of a foot may be judged. A flexible, low arched foot may be a much more useful and comfortable foot than a foot with a high arch. It is largely a question of the muscle balance. There are no true bony keystones in either the longitudinal or the transverse arches. The ligaments that maintain the arches will give way unless sufficient and prop-

erly balanced muscular support is provided. The weight bearing lines of the foot in action largely determine whether or not foot strains and symptoms of general tire may be expected to result from long continued standing or walking. An unnecessary support is a source of weakness rather than of strength and should be avoided. It is for physicians to determine whether an artificial foot support is or is not indicated.

For the foregoing reasons the Council on Physical Therapy of the American Medical Association wishes to inform the medical profession and the manufacturers of shoes that it will receive for consideration only those makes of shoes the manufacturers of which agree to make no therapeutic claims for their product in advertising to the public. If the therapeutic claims made in advertising to the medical profession are considered by the Council to be justified, and the standards of manufacture are satisfactory, the product will be eligible to be placed on the accepted list.

The Council has passed the following motion: "The Council will place on the accepted list shoes the manufacturers of which confine their therapeutic claims in advertising to the profession, provided these claims can be justified. Any therapeutic claims made in advertising to the public will disbar the product from Council consideration."

Council on Pharmacy and Chemistry

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORT PAUL NICHOLAS LEECH, Secretary

McKESSON'S VITAMIN CONCENTRATE OF COD LIVER OIL OMITTED FROM N N R

The period of acceptance for McKesson's Vitamin Concentrate of Cod Liver Oil expired with the close of 1933. While the Council was considering the eligibility of this product for continued inclusion in New and Nonofficial Remedies it was brought out that McKesson & Robbins, Inc., in the lay advertising of another product containing vitamin A, was making unacceptable claims for the use of this vitamin.

An advertisement clipped from the Chicago Daily News of Nov. 23, 1934, dealing with 'McKesson's Vitamin Concentrate Tablets' has been received in the Council's office. This advertisement, as well as others of which the Council's office is cognizant, makes direct claims for the "anti-infective" value of vitamin A in connection with "colds." For instance, in the specific advertisement referred to, the heading is "5426 Chicagoans will catch cold tomorrow." In the text of the advertisement occur the following objectionable statements: "Those fortunate people with plenty of vitamin A in their systems are surprisingly free from 'colds'"; "Fight colds the vitamin way." Another advertisement has a heading such as "Vitamin A keeps colds at bay."

The secretary called the firm's attention to this practice and the firm replied as follows:

We wish to acknowledge receipt of your letter of November 20th in which you comment on our advertisements appearing in the newspapers covering McKesson's Cod Liver Oil Concentrate Tablets. McKesson's Cod Liver Oil Concentrate Tablets have not been submitted to the Council and we believe that through some oversight you are confusing them with McKesson's Liquid Concentrate of Cod Liver Oil which is before the Council now for acceptance.

We trust that the above explains the situation fully.

The Council has had under consideration a product submitted as 'McKesson's Cod Liver Oil High Potency', the product 'McKesson's Cod Liver Oil Concentrate Tablets' has not been presented for consideration. In view, however, of the unwarranted claims made for the vitamin A content of the latter, the Council cannot continue the inclusion in New and Nonofficial Remedies of the previously accepted McKesson's Vitamin Concentrate of Cod Liver Oil nor consider further the liquid cod liver oil until the firm's advertising claims for vitamin A are uniformly acceptable. The public cannot be expected to dis-

criminate between claims made for an accepted and an unaccepted product of therapeutically identical composition

When the firm was informed of the Council's reaction, it replied that the lay advertising in question could not be corrected promptly because it was part of a series that had already been arranged for with publications. The firm stated that it would try to modify the advertising after the winter season has passed and to meet certain other requirements that the Council had found necessary to the continued acceptance of McKesson's Vitamin Concentrate of Cod Liver Oil. Since the Council was unwilling to be put in the position of condoning the making of unacceptable claims it voted to omit McKesson's Vitamin Concentrate of Cod Liver Oil from New and Nonofficial Remedies without prejudice to reconsideration when the firm has made its advertising claims for vitamin A acceptable for all products containing that vitamin.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

WARRANTY SIEVED ASPARAGUS

Manufacturer—The Nielsen Corporation, Ltd, Oakland Calif

Description—Sieved asparagus prepared by efficient methods for retention in high degree of the natural mineral and vitamin values. No added sugar or salt.

Manufacture—The asparagus is harvested when the growth shows good color, succulence and proper degree of maturity and delivered to the plant, where it is prepared and canned the same day by essentially the same procedure as described for Warranty Sieved Spinach (THE JOURNAL, Feb 2, 1935, p 399).

Analysis (submitted by manufacturer) —

	per cent
Moisture	91.7
Total solids	8.3
Ash	0.9
Sodium chloride	0.1
Fat (ether extract)	0.1
Protein (N × 6.25)	3.4
Reducing sugars as invert sugar	1.2
Sucrose	0.2
Crude fiber	0.7
Carbohydrates other than crude fiber (by difference)	3.2

Calories—0.3 per gram 9 per ounce

Vitamins—The method of preparation and processing insures the retention in high degree of the natural vitamin values.

Claims of Manufacturer—Specially intended for infants, children and convalescents and for special smooth diets. Only warming is required for serving.

- (a) "DOROTHY" BRAND STERILIZED EVAPORATED MILK (UNSWEETENED)
- (b) SUN BRAND UNSWEETENED-STERILIZED EVAPORATED MILK

Manufacturers—(a) Lang Products Sales Co, Ltd, Subsidiary of Nestle's Milk Products (Canada), Ltd., Toronto, Canada. (b) Nestle's Milk Products (Canada), Ltd., Toronto, Canada.

Description—Unsweetered, sterilized evaporated milks.

Manufacture—The same as Alpine Lion and Every Day Brands Sterilized, Unsweetered Evaporated Milk (THE JOURNAL, Jan. 23, 1932, page 319).

KRIM-KO CHOCOLATE FLAVORED DRINK

Bottlers and Distributors—

Amsterdam Dairy, Schenectady, N Y
Anthony Pure Milk Company, Nashville, Tenn.
Briggs Dairy Co., Inc., Galveston, Texas
Chippewa Model Dairy, Chippewa Falls, Wis
Eskay Dairy Company, Fort Wayne, Ind
Farmers Creamery Co., Fredericksburg, Va.
Flynn Dairy Company, Des Moines, Iowa
Forest Hill Dairy, Memphis, Tenn
Graffenburg Dairy Company, Utica, N Y
Graham Brothers Dairy, Lincoln, Neb
Green's Dairy, Greenville, Texas
Ludwig-Lane Dairy Co., Toledo, Ohio
Mayfield Dairy Products Co., Mayfield, Ky
Merrill View Dairy, Merrill, Wis
Mount Vernon Dairy Co., Inc., Irvington, N J
Quality Dairy, Inc., St. Cloud, Minn.
Queen City Dairy, Inc., Cumberland, Md.
Quincy Cooperative Milk Producers Association, Quincy, Ill
Seeger's Dairy, Silver Creek, N Y
Soldwedel Dairy Company, Pekin, Ill
Southwest Dairy Products Company, Fort Worth, Texas
Sunlite Properties Corp., Inc., Eau Claire, Wis
Superior Dairies, Inc., St. Augustine, Fla.
White Mountain Creamery Co., Lima, Ohio
Zapp's Dairy, New Albany, Ind

Licensor—Krim-Ko Company, Chicago, manufactures the Krim-Ko Chocolate Flavored Drink Base and licenses its use, the name Krim-Ko, and standard advertising under definite contract conditions.

Description—Pasteurized chocolate flavored sweetened skim milk, contains skim milk (from 0.5 to 1.5 per cent milk fat), sucrose, chocolate and cocoa, tapioca flour, salt and traces of tartaric acid and agar, flavored with imitation vanilla. See Krim-Ko Chocolate Flavored Drink, THE JOURNAL, June 30, 1934, page 2187.

HAWAIIAN FINEST QUALITY PINEAPPLE JUICE (UNSWEETENED)

- (1) COLLEGE TOWN BRAND
- (2) FLAGSTAFF BRAND

Distributors—(1) Lefkowitz-Elias Company, New Brunswick, N J. (2) Greenspan Brothers Company, Perth Amboy, N J.

Packer—Hawaiian Pineapple Company Ltd, San Francisco

Description—Canned Hawaiian pineapple juice retaining in high degree the natural vitamin content, the same as the accepted Dole Hawaiian Finest Quality Pineapple Juice (Unsweetered) (THE JOURNAL, June 3, 1933, p 1769).

CELLU JUICE-PAK CRUSHED PINEAPPLE

PACKED IN UNDILUTED JUICE WITHOUT ADDED SUGAR

Distributor—The Chicago Dietetic Supply House, Inc., Chicago

Packer—Hawaiian Pineapple Co, Ltd, San Francisco

Description—Processed peeled and cored crushed pineapple packed in undiluted juice without added sugar.

Manufacture—The method of manufacture is essentially the same as for Paradise Island Brand Hawaiian Finest Quality Pineapple (Crushed) (Dole 1) (THE JOURNAL, April 8, 1933, p 1106). Unsweetered pineapple juice is used to fill the cans.

Analysis (submitted by distributor) —

	per cent
Moisture	85.5
Ash	0.5
Fat (ether extract)	0.03
Protein (N × 6.25)	0.5
Crude fiber	0.4
Carbohydrates other than crude fiber (by difference)	13.1

Calories—0.5 per gram 14 per ounce

Claims of Distributor—Packed in undiluted pineapple juice without added sugar.

MEDICAL LICENSURE STATISTICS FOR 1934

ANNUAL PRESENTATION OF LICENSURE STATISTICS BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

The report presented herewith for the year 1934 deals with statistics regarding (a) medical licensing boards of the United States, including the District of Columbia and territories and possessions of the United States, (b) boards of examiners in the basic sciences, and (c) the National Board of Medical Examiners.

Official reports have been contributed by the officers of the medical licensing boards of all states, the District of Columbia, Alaska, the Canal Zone, Hawaii, Puerto Rico and the Virgin Islands, the homeopathic examining boards of Connecticut, Delaware and Maryland, the eclectic board in Arkansas, the nine basic science boards (Arizona, Arkansas, Connecticut, District of Columbia, Minnesota, Nebraska, Oregon, Washington and Wisconsin), and the National Board of Medical Examiners. The homeopathic boards of Arkansas and Louisiana licensed none during the year. Acknowledgment is tendered the officers of the foregoing boards for their ready cooperation and the complete reports they have furnished.

The data supplied were also entered in the biographic file of physicians and others maintained by the American Medical Association, thus serving a dual purpose. We take this opportunity also to thank the officials of the boards for other invaluable assistance rendered the Association throughout the year.

The tables showing medical licensing board results include figures regarding the number of candidates examined for medical licensure in 1934, the number licensed and the number added to the profession.

LICENTIATES

The first table shown contains figures on the number of licenses issued in the various states, territories and possessions during the year. There were 7,703 licenses issued, 5,586 on the basis of examination and 2,117 by endorsement of credentials. In several states (table 6) the internship is a requisite for practice, but a physician is permitted to take the examination and if successful his license is withheld until completion of his internship. This is particularly true in Iowa and Michigan. Licenses are also withheld for lack of citizenship or minor technicalities. The figures therefore, for those licensed after examination include many who were examined in 1933 and even a few in previous years. New York issued the largest number of licenses, 1,290, Pennsylvania issued 520, Illinois 458, California 418, Ohio 397, and New Jersey 332. A comparison with similar figures for 1933 indicates that New York issued 236 more licenses in 1934, Pennsylvania 13, California 1, Ohio 28, New Jersey 22, and Illinois 2 less.

Five states issued more than 200 licenses and twelve more than 100. One physician was licensed after examination in New Mexico and Wyoming. Florida grants licenses only on the basis of examination. Massachusetts and Rhode Island have no reciprocity privileges but endorse diplomates of the National Board of Medical Examiners. The total number licensed, 7,703, was 554 more than in 1933. This figure, however, does not represent 7,703 individuals, since several have been licensed in more than one state during the

year. Nor does it represent additions to the medical profession at large, since the 2,117 licensed by endorsement, with the exception of several licensed in New York on the basis of foreign credentials, have migrated from another state. Table 4 shows how many of those licensed were never before registered and therefore represent the number added to the medical profession.

TABLE 1—Licentiates—1934

	Licensed on Basis of		Total
	Examination	Reciprocity and Endorsement	
Alabama	20	30	50
Arizona	7	12	19

Totals	5,586	2,117	7,703

* Alaska, Canal Zone, Hawaii, Puerto Rico and Virgin Islands.

TOTAL EXAMINED

In table 2 will be found figures for individual states, indicating the number who passed and failed in medical licensing examinations throughout the year. There were 6,130 examined, of whom 5,613 passed and 517 failed. There were represented graduates from sixty-seven approved medical schools in the United States and nine in Canada, sixty-six medical schools of other countries, twenty-one medical schools now extinct, eight unapproved institutions and several osteopathic colleges. These statistics contain figures regarding only those osteopaths granted the privilege to practice medicine surgery or both by the medical board. Four under-

(CONTINUED FROM PAGE 1505)

graduates also were examined. There were 5,413 graduates of approved medical schools in the United States examined, of whom 4 per cent failed, 114 Canadian graduates, 16.7 per cent of whom failed, 286 foreign graduates with 40.6 per cent failures, 27 who graduated from schools now extinct, with 40.7 per cent of failures, and 290 from unapproved and osteopathic schools, of whom 54.1 per cent failed. Of these 290, 82 were graduates of osteopathic schools, of whom 50 per cent failed, 204 were graduates of unapproved schools, of whom 89 passed and 115, 56.4 per cent, failed, and 4 undergraduates were examined of whom 3 passed and 1 failed. Graduates of osteopathic schools were examined in Colorado, Connecticut, Massachusetts, Texas, Wisconsin and Wyoming, while graduates of unapproved schools were examined in Arkansas (eclectic board), California, Illinois, Massachusetts and Hawaii. Massachusetts registered fifty-four and Illinois thirty-three of these practitioners.

The largest number of graduates of any one school represented was from the University of Illinois College of Medicine, 167, who were examined in fourteen states. Georgetown University School of Medicine had 164 graduates before licensing boards, of whom 15.2 per cent failed. They were examined in twenty states. The next highest number of graduates from any one school was Jefferson Medical College, which had 163 graduates examined in twenty-two states, of whom eight failed. Graduates of Northwestern University Medical School and Rush Medical College were examined in twenty-nine states. Harvard graduates were examined in twenty-eight states and the University of Pennsylvania in twenty-five. From these statistics one might infer that these schools educate more non-residents than do other schools. All the graduates of the University of Southern California School of Medi-

cine represented, twenty-five, were examined in California. None failed. Graduates of Wayne University, Albany Medical College, University of Texas and Dalhousie were examined in three states. Two graduates of the University of Alberta were examined in two states. The one eclectic board in existence, in Arkansas, examined and licensed one candidate. Canadian physicians took the test in twenty-three states and one territory.

The 6,130 candidates examined do not represent individuals, since a candidate might possibly take the examination in more than one state and would be counted in each state. The same is true of the failures, but if a physician fails more than once in a given state within the year he is counted in that state only once.

The United States Postal authorities are at present conducting an investigation into widespread circulation of alleged fake medical and chiropractic diplomas and licenses. The spurious papers were found in several states, principally Arkansas. As a result, the following have been indicted, according to newspaper reports:

A. E. Wrebs, former St. Louis chiropractor, George M. Lindsay of Kansas City, his stepson, G. Martin Lindsay Jr., Dr. Date R. Alexander, former head of the Kansas City College of Medicine and Surgery, the charter of which was revoked in 1926 on the charge of its being a diploma mill, Dr. Claude E. Laws, former secretary of the Arkansas Eclectic State Medical Board, Mrs. Myrtle Long, former secretary of the Iowa Board of Chiropractic Examiners, William T. Gallagher of Kansas City, and John E. Hamilton of Fort Worth, Texas. Wrebs pleaded guilty, according to the report but sentence was deferred. The charge, it is said, is punishable on conviction by a maximum penalty of five years' imprisonment or a \$5,000 fine or both. A number of licenses have already been revoked in Arkansas.

P = Passed F = Failed

* Alaska Hawaii Puerto Rico and Virgin Islands

Three of the five homeopathic boards in existence, Connecticut, Delaware and Maryland, examined ten candidates, all of whom passed.

In 1933, 5,664 were examined, of whom 5,235 passed and 7.6 per cent failed, as compared with 6,130 examined in 1934, of whom 5,613 passed and 8.4 per cent failed. There were 466 more examined than in 1933, of whom 378 passed and 88 failed.

REGISTRATION BY RECIPROCITY AND ENDORSEMENT

The number of physicians granted licenses to practice medicine and surgery without examination are given in table 3. There were 2,096 so registered who presented licenses from other states, Canada and foreign countries, the certificate of the National Board of Medical Examiners, one of the government services or other credentials.

In an increasing number of states the boards now accept a physician's credentials, if satisfactory, whether or not the state board issuing the original license returns the favor. The following twenty-nine states and the District of Columbia generally will register without examination, licensees who present satisfactory evidence of good moral character and practice record, and, in addition, credentials which correspond to those required by their respective states at the time such licenses were issued.

Alabama	Maryland	North Carolina
Arizona	Michigan	Oklahoma
California	Minnesota	Oregon
Colorado	Missouri	Pennsylvania
Connecticut	Nebraska	South Carolina
Delaware	Nevada	South Dakota
District of Columbia	New Hampshire	Texas
Georgia	New Jersey	Utah
Idaho	New Mexico	Vermont
Maine	New York	Wisconsin

California (when ten or more years has intervened) Connecticut Illinois, Minnesota Nevada North Carolina and South Dakota require a practical or oral

examination of reciprocity candidates before a license is granted by this means. Applicants in Idaho are required to pass either a written or an oral examination in medical jurisprudence as pertaining to practice in that state.

Florida, Massachusetts and Rhode Island do not have reciprocal or endorsement arrangements with any state.

New York granted the greatest number of licenses by endorsement of credentials in 1934 (456). New Jersey was second with 157, Ohio third with 125, California fourth with 118, and Texas and Illinois fifth with 89. The largest group presenting the same type of credentials were the 389 diplomates of the National Board of Medical Examiners, the next greatest number (114) came from Maryland, Illinois was third with 111, and Tennessee fourth with 109. Only 105 New York licenses were endorsed during the year, while New York State licensed 456. Of this total, 130 were registered on the basis of foreign licenses or diplomas giving the right to practice in the country in which issued.

Nine physicians were licensed on the basis of Canadian credentials (New Mexico one and New York eight) and 122 were registered by endorsement of European credentials from Austria six, Czechoslovakia one, France two, Germany 105, Hungary two, Italy two, Rumania one, Switzerland two and the Union of Socialist Soviet Republics one. Two physicians were registered by endorsement of licenses issued in Puerto Rico.

One candidate each was licensed by the homeopathic boards of Delaware and Maryland. In addition, twenty-one osteopaths were granted licenses to practice without examination. Seventeen so registered in Texas were granted privileges as physicians and surgeons, while three in Wisconsin and one in Wyoming were licensed to practice osteopathy and surgery.

TABLE 3—Physicians Licensed by Reciprocity and Endorsement—1934

[illegible]

* Alaska Canal Zone Hawaii Puerto Rico

The four in the column headed "Miscellaneous" represent one each licensed in New York and Vermont on the basis of their medical diploma and two registered in the Canal Zone on the basis of their medical credentials in general. Diplomates of the National Board were registered without written examination in thirty-five states, Hawaii and Puerto Rico. Illinois licentiates were registered in thirty-one states also while the state that had the highest number of its licenses endorsed, Maryland, had its 114 licentiates registered in twenty states, forty-four went to New York State. New York had the greatest number of its licentiates registered

* Alaska Canal Zone Hawaii and Puerto Rico

in any one state, fifty-six, who were given the right to practice in New Jersey. Arizona, Connecticut, Delaware, Florida, Idaho, Maine, Montana, Nevada, New Mexico, North Dakota, Rhode Island, South Carolina, South Dakota, Utah and Wyoming had less than ten of their licentiates endorsed to other states and New Hampshire had none.

CANDIDATES ADDED TO THE PROFESSION

In table 4 are recorded the number of candidates added to the profession during 1934. The number represents candidates examined in 1934 and licensed also those examined in previous years whose licenses were withheld and issued in 1934, those certified on the basis of the certificate of the National Board of Medi-

cal Examiners, government services, Canadian and foreign credentials, and miscellaneous. In the main they represent recent graduates. Altogether, 5,435 were added to the profession as contrasted with approximately 3,400, the number removed by death in 1934. These figures indicate that at least 1,800 have been added to the already overcrowded medical profession. It is assumed that by far the great majority of those licensed are in practice. It is interesting to

TABLE 5—State Requirements of Premedical Training

Two Years of College

High School Graduation or Its Equivalent		
Delaware	Missouri	Ohio
Massachusetts	Nebraska	

note that, of 7,703 licenses issued throughout the year 1934, 70.6 per cent, are actual additions to the medical profession. The ratio is about twice as great as it is in England, France or Germany. The proper adjustment of the ratio of physicians to population is a matter of vital public concern. Figures compiled in 1934 indicated that the ratio was one to 814. It is to be hoped that this ratio will remain constant or be gradually decreased.

The largest number added to the profession was in New York, 1,025. Pennsylvania added 439 and Illinois 367, New Mexico and Wyoming added one and Arizona and Nevada added two.

North Dakota	1918	Wisconsin	1927
Oklahoma	1933	Wyoming	1931
Oregon	1933		

STATE REQUIREMENTS OF PRELIMINARY EDUCATION

Although, for seventeen years, two years of pre-medical college training has been required by every class A medical school, there are still eight states which have failed to adopt this standard. Statutory requirements are shown in table 5.

In table 6 will be found the states that require the internship as a prerequisite for medical licensing boards. Seventeen states, Alaska and the District of Columbia exact this requirement.

COMPARISON WITH OTHER YEARS

In table 7 are listed the numbers of candidates examined in the various states, territories and possessions in the past five years, showing those who passed and failed. In this period New York examined 4,718 candidates, Pennsylvania 2,265, Illinois 1,967, Massachusetts 1,739, California 1,571, Ohio 1,337 and Michigan 1,202. All others examined less than 1,000. The smallest number (five) were examined in New Mexico. The percentage of candidates who failed in

the examinations in the past five years is given in the last column. The proportion of failures in all the states has increased from 5.7 per cent in 1930 to 8.4 per cent in 1934. In the five year period, 38 per cent of the applicants failed in Massachusetts, followed by New York with 16.4 per cent, Connecticut 14.3 per cent, Delaware 13.6 per cent, Nevada 12.5 per cent and Florida 11.5 per cent. The high percentage in Massachusetts is due to the fact that by law they are required to admit to their examination the graduates of unapproved medical schools, many of whom repeatedly fail though they eventually become licensed. On the other hand, Idaho, Kansas, Montana, Nebraska, New Hampshire, New Mexico, Oklahoma, South Carolina, South

Dakota, Utah and Vermont reported no failures, while Arkansas, Georgia, Iowa, Louisiana, Maine, Michigan, Minnesota, Missouri, Tennessee and Texas had less than 1 per cent of failures. A total of 28,630 candidates were examined in the five years from 1930 to 1934 inclusive, of whom 26,592 passed and 2,038 failed. These figures represent examinations given and not individuals. A candidate who fails more than once in

TABLE 8—Registration—1904-1934

a given year has not been counted twice, but should he fail in one of the succeeding years he is counted in that year also. Likewise, if a candidate fails and later passes, whether in the same or a later year, he is counted as passed and failed. With a total of 2,038 failures for the five year period, it seems likely that there were approximately 25,000 individuals examined. It is to be assumed that the majority of those who fail are later reexamined and licensed in some state. This

TABLE 9—Source of Physicians Registered—1922-1934

1934	7,119	92.1	611	7.9	7,730

figure, therefore indicates a fair estimate of the number of physicians added to the profession each year. Table 4 gives exact totals on this point for the years 1933 and 1934.

REGISTRATION 1904-1934

A study of totals and percentages (table 8) for each year beginning with 1904 is of interest. The number (5,613) who passed in 1934 was 378 more than the number who passed in 1933 and only sixty-three less

STATES LICENSING OTHER THAN GRADUATES OF APPROVED MEDICAL SCHOOLS--1934

The figures indicate the number licensed

than in 1904. The number licensed without examination, 2,117, was 153 more than in 1933. Contrasting these figures with those for 1904 will show the great use being made of this system of licensure. By all methods, 7,730 were registered, 531 more than in 1933.

Of those examined, 7.6 per cent failed in 1933, while 8.4 per cent failed in 1934. While these figures represent those registered in the years given, they do not in all states represent the number licensed. Licenses are withheld in many states, as indicated in the text describing table 1.

It will be seen that there has been no constant increase or decrease in the total number of candidates registered from 1904 to 1933, although since 1906 the number licensed without examination has been increasing and those examined has diminished, owing to the universal system of endorsement. The decrease in the number registered in 1918 was, of course, due to the sudden withdrawal of physicians and recent graduates from civilian life. Again in 1922 there was a notable reduction, this figure representing the small class that began the study of medicine in 1918. There was, however, a substantial increase in the number registered in 1934, the majority having been by examination. This is probably accounted for by the fact that medical schools are graduating larger classes, 5,038 in 1934. The Council is concerned over this problem and, after it was found that many schools are accepting students in excess of the number for which satisfactory facilities are provided, at its February meeting requested the secretary to call to the attention of the deans of medical schools the following paragraph from its Essentials of an Acceptable Medical School:

The number of students to whom an adequate medical education can be given by a college is related approximately to the laboratory and hospital facilities available and to the size and qualifications of the teaching staff. A close personal contact between students and members of the teaching staff results in an efficiency which is not possible in an institution where the number of students is excessive.

SOURCE OF PHYSICIANS REGISTERED

The educational fitness of the persons registered in the last thirteen years is shown in table 9. Of the 7,730 registered by all methods in 1934, 7,119, or 92.1 per cent, graduated from approved medical schools and there were 611, 7.9 per cent, other practitioners registered. For purposes of these statistics all schools rated as class A and B since 1907 are classified as approved. In the column "Others" are included graduates of institutions prior to 1907, of foreign medical faculties, class C graduates, undergraduates, osteopaths, and graduates of schools that have been refused all recognition as medical schools.

GRADUATES OF OTHER THAN APPROVED MEDICAL SCHOOLS REGISTERED

In table 10 will be noted the total number of graduates of osteopathic colleges and those institutions which have been classified as unapproved, who were registered with or without examination in two years. In 1934, twelve states and Alaska registered 103 graduates of unapproved medical schools and six states registered sixty-two osteopaths. Of those examined, ninety-four were graduates of unapproved medical schools and forty-one were osteopaths. Twenty-one osteopaths and nine graduates of unapproved medical schools were registered by endorsement. Three nongraduates were registered. As will be noted, the sixty-two osteopaths

were registered in Colorado, Connecticut, Massachusetts, Texas, Wisconsin and Wyoming. In this connection the following facts are of interest.

In Colorado, osteopaths are admitted to the examination for a license to practice medicine. They have no separate board. The statute of Colorado is silent with respect to the scope of practice authorized by a license issued to osteopaths.

The Connecticut statute provides that any registered osteopath may practice either medicine or surgery or both, as the case may be, after passing a satisfactory examination before the medical examining board.

The Massachusetts statute, by definition, includes osteopathy in the practice of medicine but does not differentiate the type of license issued to an osteopathic applicant. The medical practice act requires that any

applicant for a license to practice medicine must be in possession of a degree of doctor of medicine, or its equivalent, from a legally chartered medical school that gives a full four-year course of instruction of not less than thirty-two weeks in each year.

The statutes of Texas provide for the issuing of a license to practice medicine only. So far as the statutes indicate, the osteopaths are not restricted in their field of practice. The medical practice act requires that the applicant be a graduate of a reputable school whose entrance requirements and course of instruction are as high as those adopted by the better class of medical schools and whose course of instruction embraces not less than four terms of eight months each.

In Wisconsin there is one licensing board. A license issued to osteopathic candidates authorizes them to practice osteopathy and surgery.

In Wyoming, osteopaths are granted the right to practice surgery.

The 103 graduates of unapproved schools were licensed in twelve states and Alaska, namely, Arkansas,

California, Florida, Idaho, Illinois, Massachusetts, Mississippi, New Jersey, Ohio and Texas Arkansas, California, Florida, Idaho, Mississippi, Ohio and Alaska each licensed one. In most of these states there was a specific reason for registration. Texas registered two and New Jersey four. Three nongraduates were registered in Kansas, Kentucky (limited license) and Mississippi (by special act of the legislature). Illinois recognizes a medical school that is not in good standing with other state boards. The Massachusetts law has already been described. These data for 1934 are illustrated also by a chart.

It is to be regretted that some states, even in small numbers, grant licenses to individuals unacceptable to the medical profession. The medical profession should be ever watchful and untiring in its efforts to prevent osteopaths from gaining the legal right to practice medicine or surgery, for which their training is wholly inadequate.

The figures showing the states that licensed other than graduates of approved medical schools in 1933 are also shown. For the two year period, twenty-two states, the District of Columbia and Alaska admitted 311 such individuals to the practice of medicine. 120 osteopaths and 191 graduates of unapproved medical schools. Four more osteopaths were registered in 1934 than 1933 and fifteen graduates of schools not recognized.

The Council on Medical Education and Hospitals is now engaged in a resurvey of all medical schools. All schools of medicine in the United States and Canada will be visited. This survey conducted under the auspices of the Council on Medical Education and Hospitals by Dr. H. G. Weiskotten of Syracuse is a very comprehensive one, three and four days being required to complete a school. Assisting in the inspections are the Association of American Medical Colleges and the Federation of State Medical Boards of the United States. By the end of the college session, forty-five medical schools will have been visited. The findings of the Council should be of assistance to licensing boards.

GRADUATES OF FACULTIES OF MEDICINE ABROAD

Graduates of faculties of medicine in countries other than the United States and Canada, examined for licensure in 1934, are presented in table 12. Sixty-six medical schools of eighteen European, two Latin American and three countries in Asia were represented. There were 285 examined, of whom 170 passed and 40.2 per cent failed. Not included in this table is one graduate of the University of Santo Tomas College of Medicine and Surgery, who failed in California. This was an increase of eighty-five over 1933, when 200 were examined, 129 passed and 35.5 per cent failed.

Data secured during the last several years indicate that there are approximately 2,000 American students studying abroad who apparently plan to return to the United States to practice. In view of the problem created by this migration, the Federation of State Medical Boards in February 1933 adopted a resolution to the effect that no student matriculating in a European medical school subsequent to the academic year of 1932-1933 will be admitted to any state medical licensing examination who does not present satisfactory evidence of premedical education equivalent to the requirements of the Association of American Medical Colleges and the Council on Medical Education and

Hospitals, and graduation from a European medical school after four academic years of attendance, and further submits evidence of having satisfactorily passed the examination to obtain a license to practice medicine in the country in which the medical school from which he is graduated is located

This policy of the Federation has been made effective by individual action on the part of the state licensing bodies and the National Board of Medical Examiners and will have its desired effect in the future

For the purpose of keeping closely in touch with developments in other countries a joint committee was appointed representing the Council on Medical Education and Hospitals, the Federation of State Medical Boards of the United States the New York Board of Regents, the National Board of Medical Examiners, and the Association of American Medical Colleges This committee has functioned and, it is believed, has been of some assistance

Further, in 1934 the Federation of State Medical Boards passed a resolution to the effect that the Federation recommend to its constituent state boards and to the National Board of Medical Examiners that, until adequate information is available, these boards deny graduates of foreign medical schools admission to the various medical licensure examinations

These various endeavors should tend to stop the flow of American students to European countries, since, it has been pointed out, schools in this country are producing more physicians than the country needs and there are more physicians in the United States than are needed to provide adequate medical service

This exodus of American students to Europe began in 1929 The time seemed opportune to analyze those graduates of foreign faculties applying for registration While it is not possible to ascertain with absolute accuracy the American born graduates, a table is presented (table 13) which shows the number of graduates of medical faculties abroad licensed in 1934 who represented additions to the profession They are classified according to premedical training Those who obtained this training in the United States are in all probability citizens of the United States There were sixty-five such individuals registered and 163 with foreign credentials who are probably foreign born The great majority of the latter group were licensed in

New York and were graduates of German faculties The Federation's rulings do not apply to native born Europeans

In table 11 are assembled figures showing the standing during the five year period 1929-1933 of the graduates of faculties of medicine outside the United States and Canada admitted to licensing examinations in this country A similar tabulation is presented for the year 1934 One hundred and twenty-seven schools are included and nine of the licensing corporations of Great Britain During the five year period 916 were examined and 285 in 1934 The largest number examined represented the Regia Universita di Napoli, 117, of whom 65.8 per cent failed, the Universität Wien in the five year period was second (sixty-three) and the University of Edinburgh was third (fifty-six), while there were fifty in the Regia Universita di Roma A study of the percentage failed is of interest

Here again an attempt has been made to show procedure over a period of years, and if an individual fails or is examined in various years he is recorded as such for a given year

NATURALIZATION A REQUISITE FOR LICENSURE

In twenty-nine states there is a requirement that the applicant must either be a naturalized citizen, have taken out first papers or declared intention of becoming a citizen, before a license to practice medicine will be granted The states of Arkansas, Georgia, Kansas, Kentucky, Nebraska, Oklahoma, South Dakota, Tennessee and Wyoming require naturalization Thirteen states require that first papers shall have been taken out, namely, Alabama, Florida, Louisiana, Maine, Maryland, Michigan, Minnesota, Mississippi, New Hampshire, North Dakota, Oregon, Virginia and Wisconsin In Idaho, Indiana (reciprocal applicants must be citizens) Nevada, New Jersey, New York, Ohio and Rhode Island the applicant must have declared his intention of becoming a citizen before being eligible for registration

BASIC SCIENCE BOARDS

Boards for the examination in the basic sciences of all those desiring to secure ultimately the right to practice the healing art functioned in eight states and the

District of Columbia in 1934, namely, Arizona, Arkansas, Connecticut, Minnesota, Nebraska, Oregon, Washington and Wisconsin A basic science law has recently been enacted in Iowa Statistics based on the number of candidates certified in 1934, and those who failed to secure this certification, together with totals for other years, are included in the accompanying tabulations

The subjects in which examinations were conducted are listed in table 1

As indicated in table 2, 866 candidates were examined by the nine boards in operation Of this number 815

were doctors of medicine and medical students (referred to hereafter as physicians), thirty osteopaths and thirteen chiropractors, and for eight it was not possible to determine what profession they represented. Of the physicians examined, 11 per cent failed, 36.7 per cent of the osteopaths failed and 69.2 per cent of the chiropractors, and of those unclassified 62.5 per cent. There were 725 physicians who passed, nineteen osteopaths, four chiropractors and three unclassified

* Effective January 1 1934

Minnesota examined the largest number, 167, of whom 26.3 per cent failed, while Wisconsin examined 140 and had only 0.7 per cent failures. Arizona, on the other hand, examined only thirty-five, of whom 28.6 per cent failed. Of osteopaths, Minnesota examined the highest number, eleven, and Wisconsin examined seven. Minnesota and Washington each examined six chiropractors. Of the total number of applicants examined, 13.3 per cent failed.

TABLE 3—Certificates Issued by Examination, Reciprocity and Endorsement—1934

	Examination				Reciprocity and Endorsement				Registered
	Physicians or Med Students	Osteopaths	Chiropractors	Unclassified	Physicians	Osteopaths	Chiropractors	Unclassified

Washington	87	1	1	0	89	0	0	0	89
Wisconsin	133	0	0	0	139	34	7	0	180
Totals	725	19	4	3	751	121	9	2	883

The number of certificates granted by examination, reciprocity and endorsement are listed in table 3. A total of 751 certificates were granted after examination, of whom 725 were physicians, nineteen osteopaths, four chiropractors and three who were unclassified. There were 132 candidates certified without examination, by reciprocity or endorsement, consisting of 121 physicians, nine osteopaths and two unclassified. Minnesota accepted the greatest number without examination, sixty-five, all of whom were physicians, while Wisconsin registered thirty-four physicians.

Table 4 shows the number of candidates examined and certified from 1927 to 1934 inclusive. In 1934, 11 per cent of physicians failed, as compared with 49 per cent of nonmedical practitioners. In 1928, when five boards were functioning, there were 646 physicians examined, of whom sixty, or 9.3 per cent, failed and fifty-nine nonmedical practitioners, of whom twenty-eight, 47.5 per cent, failed. In 1934, 846 physicians and thirty-seven other practitioners were certified. During the eight year period a total of 5,057 physicians were examined, of whom 10.8 per cent failed and 521 other practitioners, of whom 51.1 per cent failed. During this period, 690 physicians were certified without examination, while only thirty-eight other practitioners were so registered.

Altogether, 5,199 physicians and 293 others have been certified in the nine states. From the high percentage of failures in the nonmedical group it seems apparent that the enforcement of basic science laws affects most seriously this group. Examination of the records of a considerable number of states having basic science laws will show that before such laws were enacted the number of nonmedical practitioners appear-

ing for examination and licensure was very considerable and was growing.

The basic science board seems desirable in states having a multiplicity of examining and licensing boards. The object of these boards has been to provide a means of insuring that all candidates seeking authority to care for sick and injured people shall first possess a reasonable knowledge of the sciences fundamental to the healing art. Basic science boards are being advocated in several states and bills are pending in the legislature.

NATIONAL BOARD OF MEDICAL EXAMINERS

Statistics are herewith presented regarding the examinations and the issuance of certificates by the National Board of Medical Examiners. Similar material has been presented consecutively for seventeen years. The National Board was organized in 1915 and since 1922 has conducted its examinations in three parts: parts I and II being written examinations and part III a practical and clinical examination.

Four examinations were held in parts I and II during 1934, at which 1,241 and 633, respectively, were examined. In part I, 809 passed and 85, or 9.5 per cent, failed, and in part II, 583 passed and 50, or 7.9 per cent failed. Since 1922 a total of 11,679 examinations

have been given in part I and 5,945 in part II and up to Dec 31, 1934, 7,517 individuals have been successful in passing part I and 5,295 in passing part II. The figure 11,679 includes over the thirteen year period 2,883 who took incomplete examinations in part I and of the 5,945 who were examined in part II, 33 were incomplete. An incomplete examination is arranged for candidates taking part I at the end of their second medical year in schools whose third year curriculums include courses in one or two subjects of this part. The subjects thus postponed may be taken at any

TABLE 1—Examinations in Part III

Examinations of	Total Examined	Passed	Incomplete	Failed	Percentage Failed
1922	28	23	0	0	0.0
1923	70	75	0	1	1.3
1924	120	114	0	6	5.0

1930	419	400	0	19	4.5
1931	437	419	0	18	4.1
1932	540	521	0	23	5.1
1933	552	527	0	25	4.5
1934	581	549	0	33	5.7
Totals	4,202	3,990	1	206	4.0

examination period after the candidate has completed them in his medical school. Also listed under this heading are those who wish to spend some additional time on one or two subjects. Incomplete examinations were not included when computing percentages, since they represent neither a candidate eligible for certification nor a failure.

The figures cover the totals of each examination given during a calendar year and include some who fail and are reexamined during the same year and also some who pass parts I and II in the same year. There-

TABLE 2—Parts I, II and III, Excluding Duplications

	Total Examined	Passed	Incomplete	Failed	Percentage Failed
1922	525	381	58	86	18.4
1923	775	594	79	102	14.7
1924	978	756	69	153	16.8
1925	1,167	915	50	202	18.1
1926	1,161	930	105	126	11.9
1927	1,248	947	142	159	14.4
1928	1,430	1,101	211	118	9.7
1929	1,723	1,230	319	124	8.8
1930	2,044	1,547	322	175	10.2
1931	2,218	1,632	410	176	9.7
1932	2,341	1,849	350	187	9.9
1933	2,277	1,806	230	101	6.6
1934	2,261	1,802	329	130	6.7
Totals	20,148	15,540	2,729	1,879	10.8

fore they represent examinations conducted rather than individuals examined.

In the thirteen year period there were 1,279 failures in part I, 14.5 per cent, and 617 in part II, 10.4 per cent. The results of the examinations in part III since 1922 are presented in table 1. In 1934, 581 were examined, as compared with 552 in 1933. Of those examined, 5.7 per cent failed, while 4.5 per cent failed in 1933. During 1934, 548 were granted certificates. In 1922, twenty-eight were examined, all of whom were granted certificates. During the thirteen year period 4,202 were examined, of whom 3,995 were granted certificates and 206, or 4.9 per cent failed. Here again

a candidate having failed may subsequently receive a certificate. Since the National Board has functioned, 4,262 certificates have been granted.

The figures in table 2 represent the number of individuals examined during any one year. The classification as passed or failed, in cases in which more than one examination has been taken in a given year, was based on the results of the last examination during the year in question. For example, if in 1934 a student passed part I but later failed part II, he is listed as having failed. Taking this into consideration there were 2,261 who took the examinations of the National Board during 1934, as compared with 2,277 in 1933. Only 525 were examined in 1922. A total of 15,540 individuals passed one or more of the examinations in the thirteen year period shown and 1,879, or 10.8 per cent, failed. Incomplete examinations have been taken by 2,729 individuals, many of whom have since received certificates.

Diplomates licensed on the basis of their credentials in the United States increased from two in 1917 to 389 in 1934, 2,579 having been so licensed since the National Board was created. A total of 4,262, however, have received the certificate of the National Board. In 1934, diplomates were registered as follows:

State	Number Registered
Arizona	1
California	11
Colorado	2
Connecticut	19
Georgia	4
Idaho	3
Illinois	20
Iowa	4
Kansas	2
Kentucky	2
Maine	6

Vermont	5
Virginia	1
Washington	7
West Virginia	2
Hawaii and Puerto Rico	9
Total	389

The certificate of the National Board of Medical Examiners is granted recognition by the licensing boards of the following forty-three states and three territories:

Alabama	Indiana	Nebraska	Pennsylvania
Arizona	Iowa	Nevada	Puerto Rico
Arkansas	Kansas	New Hampshire	Rhode Island
California	Kentucky	New Jersey	South Carolina
Canal Zone	Maine	New Mexico	South Dakota
Colorado	Maryland	New York	Tennessee
Connecticut	Massachusetts	North Carolina	Utah
Delaware	Minnesota	North Dakota	Vermont
Georgia	Mississippi	Ohio	Virginia
Hawaii	Missouri	Oklahoma	Washington
Idaho	Montana	Oregon	West Virginia
Illinois			Wyoming

Some of these states, however, have additional requirements.

SATURDAY, APRIL 27, 1935

AMERICAN MEDICAL STUDENTS ABROAD

Recently there has been much discussion of the eventual fate in medical practice of a considerable number of young Americans who, finding themselves unable to obtain admittance to American medical institutions, have gone abroad and enrolled themselves in various foreign medical colleges. It seems reasonable to believe that students who follow the regular curriculum in any of the well established foreign universities and medical schools may eventually find a practical outlet for their knowledge. In other words, they may sooner or later appear before the state medical boards in some of our states and obtain licenses to practice medicine. However, this comment concerns seventy-nine Americans who are now in attendance at the Anderson College of Medicine, a so-called extramural school in Glasgow, Scotland.

The files of the Association of American Medical Colleges contain nearly 100,000 records of applications made during the years 1932, 1933 and 1934. At the request of the Council on Medical Education and Hospitals of the American Medical Association, the college association has made a study of the previous records of the seventy-nine Americans already referred to. Applications were not found for thirty-seven of the seventy-nine students. Either these students did not apply to any American institution or perhaps they applied during the years 1930 and 1931, when the study of applicants was temporarily discontinued. The remaining forty-two students had made one or more applications to an American school during the three years under consideration. Only two however, were accepted in recognized American schools, and four others were accepted in unapproved medical schools. The forty-two applicants made, in all, 651 applications, or nearly fifteen applications each. One applicant had made seventy applications during the three years concerned. This individual applied for registration with the General Medical Council in Great Britain and his credentials were forwarded to the Association of American Medical Colleges for evaluation. When

the report was sent to the General Medical Council registration was refused, but the student nevertheless enrolled in Anderson College.

What will become of these students when they complete the work in Anderson College and attempt to return to the United States to practice? Two years ago the Federation of State Medical Boards of the United States, the New York Board of Regents and the National Board of Medical Examiners adopted resolutions in accordance with which American students who graduate from European medical schools will be admitted to licensing examinations in this country only when the premedical record of the candidate has been approved in advance by one of the licensing boards and only when it has received the endorsement of either the Council on Medical Education and Hospitals of the American Medical Association or the Association of American Medical Colleges. Wide publicity was given to these resolutions in many medical publications. Moreover, the resolutions were forwarded to the General Medical Council of Great Britain. However, the extramural schools of Scotland continue to accept such students in spite of the fact that the General Medical Council of Great Britain has refused to register those who have not complied with the requirements of educational and licensing bodies in this country. Certainly it is unfair for these schools to matriculate students who they know will ultimately be ineligible for license either in Great Britain or in the United States. However, the students themselves are not exempt from responsibility.

Sooner or later most of these students will return to the United States. When they find it impossible to obtain licenses to practice, some probably will set up practice without licenses, creating for the administrative officials in the state concerned a serious problem and demanding the expenditure of considerable money in order to keep them under control. Unless state boards are watchful and adhere faithfully to the policy recommended by their own federation, some of these undesirable applicants may filter into practice in this country.

Every one knows that medical schools are being deluged with the applications of young men who wish to enter the study of medicine. The Commission on Medical Education indicated that there are already some 25 per cent too many men engaged in medical work. The colleges endeavor to select from among the numerous applications that come to them young men who will, they believe, be able to complete the medical curriculum. Nevertheless it is already a well established fact that from 10 to 15 per cent of those who enter medical college fail during their first year. The medical curriculum during the first year is probably the most difficult of that of any branch of study. Physicians, therefore, owe it as a duty to young men who seek their advice to inform them of the difficulties of gaining admission to medical schools, of the difficulties

involved in satisfactorily completing the course, of the fact that failure in one institution means almost certainly an inability to obtain entrance elsewhere, and that study abroad in unacceptable and unrecognized medical schools constitutes a waste of time, effort and money

DIAGNOSIS OF LEAD ABSORPTION

Some method of determining lead absorption in persons exposed to lead before the onset of clinical poisoning has long been desired. McCord and his co-workers¹ suggested such a method more than ten years ago, but because of technical difficulties the method has not yet been widely employed. The test is based on a search for basophilic erythrocytes, which are believed to be more numerous in the blood of those absorbing lead than in normal persons.

The technic is important. The one now employed² has overcome, they believe, the main difficulties. Thin, even blood smears are made on slides and allowed to dry. The proper drying is important since, if excessive, some of the basophil containing cells will not lend themselves to aggregation of their basophilic material. Ordinarily the optimal drying time lies between one and three hours. After drying one half of the slide is overlaid by a strip of filter paper. The filter paper is cautiously moistened with methyl alcohol until it clings to the slide. The paper is allowed to dry until it becomes loose. The slide is then submerged in a Coplin staining jar containing the stain. For the stain, a mixture of borax, boiling distilled water and methylene blue freshly prepared at least every two weeks has been found the most satisfactory. By means of an oil immersion objective and a 10 X ocular fitted with a Whipple grid, counting of the fixed and unfixed portions of the slide is easily accomplished. By choosing a corresponding number of fields the percentage of basophilic aggregations can be determined.

More than 1,600 persons were examined by this technic in 1934. Seven industries using lead and controls chosen largely from office workers were studied. In persons exposed to lead otherwise in normal health the detection of basophil containing red cells in excess of 15 or particularly 2 per cent suggests lead absorption and the possibility of approaching clinical lead poisoning. In persons exposed both to lead and to other substances such as benzene or toluene, abnormal percentages of basophil containing erythrocytes might be produced by the latter or by their combination with lead. In prolonged chronic lead poisoning the test described appears to be of restricted value. The recession of the number of basophilic aggregations is definite even in the presence of frank manifestations

of chronic plumbism. Under certain circumstances, two weeks of lead exposure is ample time to induce increased numbers of basophil containing cells. It is also possible, in the authors' opinion, to rate different departments as to the efficacy of protective devices by means of mass basophilic aggregation tests. Such tests also serve as a means of identification of those workers for whom remedial medical measures are necessary.

It is concluded, then, that the chief value of the test is as a mark of lead absorption and early lead poisoning. As lead poisoning progresses to extended chronicity, the worth of the procedure diminishes.

THE CONTROL OF PEPTIC ULCER

Probably no disease of widespread occurrence has aroused more extensive and more diverse opinions regarding its nature and treatment than has peptic ulcer. Despite an enormous amount of investigation, the cause of this condition is still unknown. The principal theories of its origin, namely, the vascular, mechanical, constitutional, infectious and neurogenic, have been discussed in a recent review.¹ It appears certain that more is involved than the local lesion in the mucous membrane, which heals spontaneously or under treatment but may later reappear. Although the course of the disease may be altered by complications, in the average case it usually does not become more severe as time goes on but tends to persist throughout life. The disease is rarely fatal and does not generally shorten life.

The methods now used in the control of peptic ulcer may be considered as medical and surgical. In a recent study² based on experience with 1,435 cases, the conclusion is drawn "that none of the present methods of treatment do more than assist in the induction of remissions, no matter how strict the medical schedule or how radical the operation." Apparently, surgical methods may produce longer periods of freedom from symptoms than medical treatment, but the former carry a definite threat to life and often produce mechanical situations that make subsequent attacks difficult to control. In the opinion of these investigators, surgical intervention should be used only to accomplish definite purposes, such as to close a perforation, to remove a permanent obstruction, to combat a hemorrhagic tendency or to treat cases in which there is a reasonable indication of cancer or malignant degeneration. Their procedure of choice is first to prevent or to minimize factors that may cause a relapse, as fatigue, worry, emotional disturbances and infection, and second to place the patient on a suitable type of medical treatment. It is wise at the outset to inform the patient frankly of the nature of his disease, that it does not seriously threaten his life and usually does not tend to progress in severity.

although it may limit his activity and perhaps cause some discomfort at times, and that although there is no certain means of permanently curing the disease there are measures that will make him more comfortable and efficient at his work. An adequate amount of rest is essential.

The diet in peptic ulcer must fulfil several requirements: it must contain all the dietary constituents recognized as essential by modern authorities on nutrition, it should consist of foods that are not too coarse, and it should contain only sparing amounts of the condiments. A comparison of certain of the medical treatments with surgical procedures² has shown that better results are obtained medically. Treatment by the "complete Sippy regimen" yielded satisfactory results in 90 per cent of the cases, the "partial Sippy" in 87 per cent, and the "five meal plus alkali schedule" in 82 per cent. Surgical treatment, on the other hand, yielded satisfactory results in from only 53 to 70 per cent of the 480 cases observed. A lack of improvement in cases treated by the three foregoing medical procedures and the surgical method was found in 51, 78, 133 and 186 to 413 per cent respectively. Extensive data furnish a convincing demonstration of the efficacy of proper medical treatment, particularly the complete Sippy regimen, in the control of peptic ulcer and its general superiority to the surgical procedure.

The value of gastric mucin in the treatment of peptic ulcer has been the subject of a number of recent investigations. Apparently, the justification for its trial as a therapeutic agent is based on the fact that mucin exerts a protective effect on the membranes with which it comes in contact by virtue of its viscous nature and perhaps because of its buffer action. Clinical use of the material has yielded beneficial results in some instances. A recent report³ based on the information derived from questionnaires concerning 494 patients with peptic ulcer treated by clinicians throughout the United States indicates that mucin therapy successfully controlled the symptoms in a large majority of the cases and failed in 7 per cent. The favorable results were striking in cases of intractable ulcers in which accepted orthodox measures including operation, had failed. Complete relief was obtained in 63 per cent of these cases, whereas 75 per cent were not benefited. However, other reports are not so favorable.⁴ One of the objections to mucin therapy appears to be that gastric mucin is extremely unpalatable,² an objection that has been exaggerated, according to some investigators³ by the failure of patients to prepare the substance in suitable mixtures so as to disguise as much as possible the distasteful qualities.

The value of certain therapeutic agents, such as gastric mucin, is yet to be adequately determined.

Current Comment

BASIC SCIENCE BOARDS

As is indicated elsewhere in this issue (page 1518) there are now nine states which have basic science boards, and a basic science law has recently been enacted in Iowa. Moreover, such laws are pending in a number of other states. The figures as to the operations of the boards are significant. Of the physicians examined by such boards last year, 11 per cent failed, of the osteopaths, 36.7 per cent failed, of the chiropractors, 69.2 per cent failed, and of those unclassified, 62.5 per cent failed. Figures of this kind should indicate more definitely than any argument the importance of establishing minimum standards of education for all who propose to heal the sick. The data indicate equally the fact that this minimum of education is not available to the vast majority of osteopaths, chiropractors and other cultists who wish to practice the healing art. The records for the period 1927 to 1934 are even more convincing. From the percentage of failures in the non-medical group, it is clear that the basic science boards render a most valuable service to the people of the states which have established such restrictions on those in the practice of medicine. The basic science board is particularly desirable in those sections which have a multiplicity of examining boards, giving the people the security that comes with the knowledge that those who practice any form of healing have at least a certain minimum qualification in the way of general education.

"A MIND THAT FOUND ITSELF"

Twenty-five years ago Clifford W. Beers¹ wrote a book called "A Mind That Found Itself." The National Committee on Mental Hygiene came into existence largely as a result of the publication of this book, which has been described by Booth Tarkington as a "unique human record of inner experience." It is the autobiographical account of a young man whose brother died of epilepsy. The young man gradually developed a fear that he might become stricken with the same disease. For five years he led the life of a neurasthenic. He finally broke down and was placed in a sanatorium. He gives a description of his life in the institution and the gradual recovery. In connection with the celebration of the twenty-fifth anniversary, the publishers have issued a new edition of the book. The new edition is supplemented with a series of letters from important people who took part in the mental hygiene movement. Associated with the publication of the new edition is another book (issued in a limited number of copies and consisting of tributes to the book) by Wilbur L. Cross and many others and also a description of the National Committee on Mental Hygiene and its activities. Today the movement is well established and gaining impetus, no doubt because the activities of this organization fill a real need.

Association News

THE ATLANTIC CITY SESSION

University of Pennsylvania Medical Alumni Smoker

During the coming annual session of the American Medical Association in Atlantic City, the Medical Alumni of the University of Pennsylvania will hold a reunion and smoker on the evening of Wednesday, June 12, at the Hotel Claridge.

Early registration of those expecting to attend is requested. Communications may be addressed to Robert A. Kilduffe, M.D., Atlantic City Hospital, Atlantic City, N. J.

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45 Chicago daylight saving time (3:30 p. m. central standard time). The next three broadcasts will be delivered by Dr. W. W. Bauer. The titles will be as follows:

May 2 Being Your Age
May 9 Saving Our Mothers
May 16 Children's Eyes

National Broadcasting Company

The American Medical Association broadcasts under the title "Your Health" on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15 Chicago daylight saving time (3 o'clock central standard time). The next three broadcasts will be as follows:

April 30 Child Health W. W. Bauer, M.D.
May 7 Mothers of America W. W. Bauer, M.D.
May 14 Training Good Doctors W. D. Cutter, M.D.

ANNUAL CONGRESS ON MEDICAL EDUCATION, HOSPITALS AND LICENSURE

Thirty First Annual Meeting held in Chicago Feb. 18 and 19, 1935

(Continued from page 1450)

The Hospital Administrator

DR. A. C. BACHMEYER, Chicago. Much of the work in x-ray and laboratory procedures can be performed by well trained, skilful technicians working under competent supervision. The final interpretation of the x-ray film, the performance of fluoroscopic examinations and the personal supervision of roentgen therapy should always be the direct responsibility of the roentgenologist, who, in addition to his basic medical training, has had further instruction, training and experience in this special field. The roentgenologist who returns his report after study of the films alone and who does not acquaint himself also with the clinical observations or personally examine the patient in many instances is not giving adequate service. Neither is the service satisfactory if the films are made by a technician and interpreted by a physician or surgeon who has not had special training in radiology.

Similar principles apply to the work of the pathologist. Much of the work can be performed by skilled technicians, but here also the final results should be checked and interpreted to the clinician by the pathologist, who has had special training beyond that given in the basic medical course. Laboratory tests and analyses made by unsupervised technicians or interns frequently are wrong. Postmortem examinations should never be made by any one except a competent pathologist. In the case of biopsy examinations it is essential that a proficient pathologist supervise or perform the technical work and personally make the examination and report. Frequently the reports emanating from the clinical or pathologic laboratory may leave the physician or surgeon in doubt or tend to confuse him. In such instances consultation with a well qualified pathologist is of great value. As in the case of the roentgenologist so here the hospital staff should number among its members a well qualified

and competent pathologist, who should be held responsible for all clinical and pathologic laboratory work performed in the institution.

The situation with reference to general anesthesia is somewhat different. The most satisfactory solution of this problem is encountered in those institutions in which a well trained physician anesthetist is selected by the surgeon but directly paid by the patient. The number of such anesthetists does not as yet suffice to meet the needs for this service. When one considers the large number of major surgical procedures performed each day in thousands of hospitals and the comparatively small number of competent physician anesthetists, it is apparent that this ideal is not everywhere obtainable at present. In the many instances, however, in which such proficient service is not obtainable, the interests of the patient demand that the services of the best trained anesthetist available be utilized. Emphasis should be placed not on the fact that the anesthetist is or is not a physician but on the training and competence of the individual. The undergraduate course in medicine in most colleges contains but meager instruction in anesthesia, and such a course alone does not provide the training and experience requisite to produce a competent anesthetist. Neither is such training obtained in the course of the usual internship. The idea that any practicing physician can satisfactorily and efficiently administer a general anesthetic is erroneous. While it may be true that the proficient physician anesthetist can relieve the surgeon of some of his anxiety concerning this phase of his responsibilities, he or she cannot relieve him of all responsibility for the anesthetic. The surgeon must be in control of the entire surgical team, and the decisions incident to all procedures during the course of the operation must emanate from him.

There is a place for the nonprofessional but well trained, skilful anesthetist in institutions at present and there will be until there are a sufficient number of physicians with special training for this service.

I have not dwelt on the economic factors that enter into this problem. Theoretically, the cost of service should be of secondary consideration. All are aware, however, of the fact that costs loom large in one's considerations at all times. I would hold to the principle that the professional man should receive adequate compensation for his services whether that compensation be derived from individual fees paid by the patient or paid in some other way. I have indicated that the former procedure has worked with most satisfaction in the case of the physician anesthetist and know that in some instances it likewise is used in the case of the roentgenologist. In the instance of the pathologist, particularly the clinical pathologist, there are many complications and except for individual laboratories apart from hospitals it does not appear to be very practical.

It appears that from the point of view of a hospital administrator that

1 The x-ray work in a hospital should be under the control of and supervised by a competent roentgenologist.

2 Likewise the clinical and pathologic laboratory service should be under the control and supervision of a well qualified pathologist.

3 The anesthesia service should, when possible, be performed by qualified physician anesthetists, but the services of well trained, skilful technician anesthetists are preferable to those of the untrained physician.

Administrative Aspects

DR. A. T. McCORMACK, Louisville, Ky. I believe that physicians should do everything that has to do with the diagnosis and treatment of disease. I think this principle is basic. Unfortunately it has been departed from to such an extent that the facts must be looked squarely in the face.

The general practitioner must under all the laws be allowed to do anything that he is capable of doing for his patients. I have found that he does everything rather better than most specialists do anything. In 80 per cent of the ills of humanity the general practitioner is far the safest adviser. I believe that one of the most unfortunate practices that have sprung up is that of people going to eminent specialists for examination without first having had the services of the general practitioner.

The discussion presents administrators of state laws with this practical difficulty. If there were enough capable pathologists, roentgenologists and urologists to do the job, nobody else would be called on by the doctor at any time. However, there are not enough. Owing to the small numbers in the several specialties, a large number of technicians have been employed. They have too frequently been permitted to do most of the work, and they have too frequently been given too little supervision both in and out of the hospital. This is a situation in which physicians must clean house before they can ask that they shall be given the responsibility and compensation for their work as long as a great deal of it is being done by others.

As between the three specialties, I feel that it is far more important for the anesthetist to be a physician. The highest court decided that a surgeon performing an operation was responsible for every act of his assistants unless they were regularly registered physicians, that he could use unqualified anesthetists at his peril and that in case an accident occurred and he was sued for malpractice he would be liable *per se*.

An amendment was passed to our law providing for the examination and registration of nurse anesthetists. There have been fewer nurse anesthetists each year since that law was passed.

In the matter of laboratory technicians, an equal difficulty was encountered. It was found that in most of the great laboratories pathologists, bacteriologists and chemists were training young men and women to prepare their specimens and carry through their technical operations. It was found that many of these laboratory technicians were connecting themselves with commercial laboratories or were opening laboratories. The law was amended to provide for the examination and registration of laboratory technicians. It is provided that in their certificates they can practice only under the supervision and direction of a registered and legally qualified physician.

In Kentucky, technicians are not pathologists, are not bacteriologists, are not roentgenologists. They are technically trained assistants for these specialists. The standards of entrance to training schools for technicians have been raised so that they are required to be college graduates. The final examination and diagnosis whether of a specimen or of a roentgenogram should be made by the physician. In Kentucky, when qualified laboratory technicians in both x-ray and pathologic laboratories have passed the examination, they are certified and can act as assistants to regularly licensed physicians or dentists and nobody else. They cannot open independent laboratories and they have no right to administer treatment; they remain technicians. Our plan is working to the satisfaction of our physicians. I insist that as physicians we shall take the responsibility for all medical service. I am convinced that anatomists, physiologists, chemists and all others teaching the fundamental sciences to undergraduate medical students should themselves be registered, qualified physicians. I am sure that much of the evil that has grown up around the giving of medical service by those who have not had medical training has come since the development of the nonmedical full time professor in medical schools.

The Licensing Board

DR. WALTER L. BIERRING, Des Moines, Iowa. The qualifications for a physician specializing in roentgenology or radiology to be approved by the Council on Medical Education and Hospitals of the American Medical Association must include graduation from an approved medical school and license to practice medicine in the state in which his department is located. He shall also have special training such as is approved by the Council, in radiology, roentgenology or radium therapy at an acceptable school—preceptorship hospital or clinic, department of radiology, roentgenology or radium therapy—for a period of at least three years or, in lieu of such training, shall have had a minimum of five years' experience in the exclusive practice of radiology, roentgenology or radium therapy. To that has recently been added certification after satisfying a qualifying examination by a special examining board in roentgenology.

An effort has been made in certain metropolitan hospitals to distinguish between x-ray operators or technicians and licensed physicians or certified roentgenologists or radiologists; the latter

acting as a consultant for the diagnosis and proper interpretation of prepared x-ray films. On the other hand, radiology may be regarded as a type of general practice conducted by a specially trained physician.

The production of roentgenograms to fulfil their full service to the patient should be prepared by a roentgenologist.

Fluoroscopic examinations and roentgen diagnosis can be assumed without argument to be medical procedures.

Roentgenology is now generally recognized as a form of specialized medical practice and comes properly within the sphere of licensure requirements.

The clinical pathologist does not imply the direct contact between patient and physician that prevails in radiology, yet the fundamental training for this service is equivalent to that required for the practice of medicine.

A service to the patient that includes diagnosis fundamental for proper treatment and prognosis is distinctly a medical procedure and should be rendered only by a licensed physician.

The administration of anesthetics, while primarily a physician's responsibility, has been delegated in many instances to specially trained nurses, assistants and other nonmedical anesthetists.

The primary consideration always is the safety of the patient, and, while experience has amply demonstrated that nurses, when properly selected and trained, can administer certain types of anesthetics as safely and satisfactorily as can physicians, they are obviously limited to the administration of ether and certain forms of gas anesthesia.

With the remarkable advancement in the knowledge of anesthetics and their dangers, particularly the introduction of different forms of local anesthesia—intravenous, rectal and intraspinal administrations—anesthesia has definitely invaded the field of medical practice.

Modern surgery owes its existence to the science of anesthesiology. Neither can exist without the other, and anesthesiology therefore is gradually being regarded as a medical specialty. The fatalities that occasionally occur in connection with ether and other forms of inhalation anesthesia incident to primary respiratory failure or sudden cardiac standstill as well as the hazards attending spinal or caudal administration brings the service of anesthesia definitely within the province of the physician.

The proper appreciation of the patient's physical condition and prompt recognition of danger signals constantly emphasizes the need of medical training.

In Iowa and a number of other states, anesthesia is regarded as a prerogative of the physician and cannot be delegated to a lay person without violation of medical laws.

The gradual acceptance of the anesthetist as a medical specialist must eventually place the responsibility of administering anesthetics of all types within the function of the licensed physician. Nurse anesthetists may be continued, for certain practical reasons, into the future to carry on anesthesia under the direction of a physician. It is however to be remembered that any act which requires medical supervision is *per se* a professional act.

The certification or licensing of qualified technical assistants in any profession or medical activity is being recognized as a necessary essential in rendering proper medical service. It seems particularly applicable in connection with the technical operation of roentgenology and clinical pathology. It can perhaps also be applied to the practice of anesthesia but to a much less degree.

Each of the practices of radiology, clinical pathology and anesthesia are assuming more and more the function of professional service and as such will eventually be governed by licensure requirements.

DISCUSSION

DR. ALBERT SOILAND, Los Angeles. Not only should the radiologist be licensed to practice medicine but clinical radiology should be one of the major subjects in every medical college that claims class A rating. Radiology is being exploited not only by the hospital, as Dr. Kirklin so well paraphrased, but by altogether too many members of the medical profession. It has always appeared uncomprehensible to me that radiology has been compelled to beg for recognition and fight for its existence as a medical specialty. From every conceivable point of view it has been an inseparable part of clinical medicine and

surgery since Roentgen announced his x-rays in 1895 and Pierre and Marie Curie produced radium in 1898. Since that time the art and science of radiology has penetrated into and become a permanently integral part of every branch or division of the healing art. Who can picture the next forty years' progress in radiant energy? Radiologists are now using short wave x-ray energy at 1,000,000 volts potential. Just five years ago the highest obtainable under actual clinical conditions was a little less than 200,000 volts. With such outstanding American physicists as Coolidge, Millikan, Lauritsen, Compton and Tuve cooperating, radiology will eventually yield its ultimate secrets so that all mankind may benefit thereby. The United States has four national radiologic bodies besides hundreds of local organizations. The minimum requirements for membership in any of these radiologic organizations are that the applicant must be a graduate from a recognized college of medicine and surgery and must have a license to practice medicine and be certified of his standing as an upright, moral American citizen by authorities in his own community. As Dr. Kirklin points out, radiology in the early days drew into its appealing fold much bad blood, and its illegitimate offspring are apparent everywhere. Recognizing this, the medical radiologist is doing everything possible to set his own house in order, hence the American College of Radiology organized twelve years ago with one thought and purpose, to found an institution which would represent professional standards that every medical radiologist should strive to achieve. Those standards are now being furthered by the work of Dr. Kirklin and his fellow members on the recently constituted American Board of Radiology. The one cloud on the horizon is that group of hospitals using laymen technicians or radiologists of questionable status who are in full control. I agree with Dr. Kirklin's outline of the Cleveland Hospital plan. There can be no separation into minor or major radiology. The simplest radiologic problem, whether diagnostic or therapeutic, is inseparably major. It is hoped that this symposium will develop a satisfactory plan whereby all hospitals may get a clean bill of health for their radiologic departments.

DR. J. J. MOORE, Chicago. I was taught that pathology was the foundation on which the superstructure of medicine was constructed, that symptoms and signs were the results of pathologic processes and that therapy was instituted to prevent, alleviate or cure pathologic changes. If a license is required for those who diagnose and treat, why should not the same be necessary for those who find the cause for diagnosis and treatment? The first group of specialists to be approved as specialists by the American Medical Association and not self-selected as in all other specialties but the radiologists were the pathologists, and this association requires them to have three years of special training after graduation and to be licensed. In addition, the American Medical Association requires that all hospitals approved for interns have autopsies performed on at least 15 per cent of those who die and that these autopsies whenever possible be performed by approved pathologists. In Chicago 500 or 600 licensed physicians gather weekly to see the material displayed by and listen to the comments on medicine of one pathologist. Would it seem right that the students should be licensed and the teacher unlicensed? The active pathologist consults daily with many physicians, he examines and diagnoses cases, he suggests methods of therapy and he frequently administers therapeutic agents. He is constantly practicing medicine and would be legally endangered if he did not have a license. Furthermore, he testifies both as a witness to fact and as an expert in medicolegal cases. For the protection of patients I believe that a law should be passed permitting only licensed pathologists to direct clinical laboratories.

DR. WILLIAM R. DAVISON, Evansville, Ind. The problem of technicians has been before the Indiana board for the past two or three years and the following instances have come up. An organization of nurses wrote a letter announcing that it proposed to open in Indiana laboratories for clinical diagnoses and would be prepared to examine all pathologic material including serologic specimens. An x-ray technician without any medical training whatever had worked in an x-ray laboratory long enough to distinguish between a Coolidge tube and a switch and then decided he would open a diagnostic laboratory. An

injured child was taken to a very capable surgeon, who found no evidence of fracture but made a diagnosis of a strain on the annular ligament of the wrist. He had no roentgenogram made and all the neighborhood busybodies persuaded the family to take the child to this technician, who, not knowing anything about epiphyses, made a diagnosis of fracture and then there was commotion. Only by taking the child to a competent x-ray man and making a picture of both wrists on the same plate were the parents persuaded that there was no fracture. The chemist of a proprietary medical company had some difficulty with the owners and withdrew, setting up a chemical laboratory for diagnosis, and offered his services to the physicians of the city. He soon was called "doctor" and was making diagnoses of various kinds. A doctor in a nearby state recently wrote a letter to the board, stating that he proposed to install in Indiana an electrocardiograph laboratory, with a trained technician in charge, who was prepared to make diagnosis of heart conditions. In all these cases the board was asked what would be its attitude and the executive officer promptly informed each one that swift prosecution would follow. These are only recent instances of the method by which such inroads have been made. The problem of the nurses in anesthesia has been before the Indiana board for the past year. It began when an anesthetist, a very capable doctor, complained because of the inroads into his practice on the part of a nurse who was paid by the hospital about \$75 per month and maintenance. The charges were made according to the accustomed rate and the hospital kept the remainder. An investigation of the law followed, and the attorney general of Indiana pointed out that a nurse in administering anesthesia was in fact practicing medicine. There has been a tendency in the past year or two for the courts to hold that a surgeon in his work must confine his efforts to that alone; that he cannot be responsible for the condition of the patient. He must have an anesthetist who is responsible for the administration of the anesthetic and the condition of the patient. Each has his proper field. This is a desirable state of affairs. Is the medical profession to abandon, step by step, various phases of its work and allow technicians and nurses to take over that work? The adversity of the last few years has no doubt played a part in this, as nurses and hospitals having decreased incomes see the opportunity to make a partial recompense. On the other hand, the physicians who have also had their adversities and have objected to this. The decisions in California and West Virginia in the past year or so have been of far-reaching influence, and I believe that other states should follow along this line.

DR. T. J. CROWE, Dallas, Texas. In Texas there are a number of unlicensed persons practicing medicine who take advantage of the situation to employ an old doctor who is unable to make a living in the practice of medicine. They pay him a salary to act as a foil for the outlaw, who surrounds himself by technicians, anesthetists, pathologists and radiologists. I had a man tell me that he walked into the office of one of them and found sixteen patients waiting to be treated. I believe that every man who has anything to do with the practice of medicine either as an anesthetist or a technician or a radiologist or what-not should be licensed and responsible for the work he does. I have now an attempt on hand to get rid of one such person as I have been talking about. We recently convicted one at Fort Worth, a man who had used the radio and was surrounded, as I have said, by technicians and by an old, discarded practitioner who got a license years ago and was a foil for this outlaw and protected him. If the technician, the anesthetist, the pathologist and the radiologist should be required to be licensed, it might be possible to enforce the medical practice act a little more effectively than it is being enforced now.

DR. AUSTIN A. HAYDEN, Chicago. I am in accord with what Dr. McCormack and Dr. Crowe have said about the restoration of every medical procedure to licentiates of medical state boards and graduates of medicine, so far as that is possible and so far as the laws of the state will permit. Beyond those limitations, I think that the road for any sort of restoration to licensed physicians must be carefully laid out and carefully followed. My own experience comes from my observation of work in three different kinds of hospitals. The first is a fifteen-bed rural hospital, the second is a fifty-bed college infirmary,

and the third is a 200 bed hospital in Chicago. Speaking from this experience on some of the things that Dr McMechan said, let me say that when I was an intern in a hospital of that sort all the anesthetics were given by doctors, but that system was found to be unsatisfactory. I have no doubt that there were errors in the method according to which the anesthetic service was set up which could be corrected, and perhaps a satisfactory system of anesthesia could be evolved. The physicians that attend the average 200 bed hospital in Chicago number about 100 and we have found it satisfactory to have a nurse that is on call continuously and well trained to do that work. I didn't know there was so much trouble about laboratories as seems to be apparent, and I didn't know there was a great deal of trouble about x-rays. I believe that these men should be the highest type of medical practitioner, but I also believe that they cannot do everything themselves, that they have to have technician assistants, and I believe it is proper for them to have them. It might be well for those technicians to be state licensed as they apparently are in Kentucky, but so far as I have observed in the operation of laboratories that is not essential.

DR I D METZGER, Pittsburgh. From a legal standpoint it must be assumed that any one who has to do with the welfare of the patient thereby assumes the responsibility and should be licensed to practice medicine. That pertains particularly to the roentgenologist and to the pathologist. In Pennsylvania a record must be made by the consultant in all cases in hospitals, by which that person is placed on the spot with respect to the opinion given in a certain case. Because of that fact the record becomes a legal document which may be used in the courts. An unlicensed person, therefore, would have no standing in the courts in such a case. Roentgenologists and pathologists are highly trained technical persons. The science of medicine enters into their work more than it does into the anesthetists' work. Anesthesia, however, concerns the art of medicine, not so much the science of it. A clever artist in anesthesia is much to be preferred to one who has a very thorough knowledge of the science of medicine and has little training in the art of practicing that particular form of medicine. I agree with Dr McCormack that the situation must be met as it is. In Pennsylvania there are some 400 hospitals. It became necessary in 1916 to take a definite stand in respect to the administration of anesthesia in our hospitals. Up until that time the cases referred to the surgeon were generally followed by the person that referred them who wanted to have a part in the operation by giving the anesthetic, and the direful effects were so great that it became necessary for the board to step in and endorse some plan by which that could be corrected. Anesthesia is a specialty in medicine. No person has a right to give an anesthetic who has not been specially trained for it. Rather than having an untrained city doctor give an anesthetic just for the sake of securing part of the fees, it is much better to have some one set aside to do that sort of thing in the hospital. The surgeons welcome this particular regime, which was established in Pennsylvania. Therefore it can be readily understood that we are almost led to the employment of persons who make that their own job and do that alone. Theoretically, I agree that the physician is the one who should give the anesthetic, provided he is a specialist in that line. Those specialists are not to be found outside the large cities and specialists cannot be developed to cover the entire state. The small fee that the anesthetists receive does not lead to the development of special anesthetists and in the smaller communities such special anesthetists might have difficulty in getting the cooperation of all the physicians of the district.

DR WILLIAM C WOODWARD, Chicago. I have listened with great interest to what has been said by those who are in intimate touch with the practice of roentgenology, pathology and the administration of anesthesia. One thing stands out and that is this. We have here a small body of highly trained specialists who seem to agree that there should be some limitation on the practice of their respective callings. On the other hand, scattered over the country are 150,000 physicians, most of whom frequently employ unlicensed practitioners to perform these duties. Obviously there is something wrong with this group or there is something wrong with the other group. The

most important reason for regulating the practice of medicine is the fact that the patient himself is not capable of exercising sound judgment in the making of a choice. On the other hand when he employs a physician he has employed some one who is supposed to be capable of making a choice as to his needs. Therefore the judgment of these physicians who employ unlicensed practitioners to do roentgenologic work or pathology and to administer anesthesia must be bad, or there is something at fault with the judgment of some of the speakers here. I am much disappointed in what has been said with respect to the dangers of the unregulated practice of roentgenology, pathology and anesthesiology, because only one instance has been cited in all the discussion in which anybody was harmed. No one will get anywhere before a legislative body without evidence of facts. It is all right for specialists to give opinion evidence, but certainly if there is any great danger in the unregulated practice of the arts and sciences there must be evidence of that fact. The medical profession should be able to assemble the facts in such a way as to show the extent to which the danger arises from a poorly equipped medical profession and the extent to which it comes from the existence of unlicensed practitioners. In 1930 in the United States there were 702 deaths recorded from anesthetics. These figures are taken from the official records of the United States Census Bureau and refer only to cases in which death was recorded as due to anesthesia. Of those deaths five were attributed to tribrom ethanol, nineteen to chloroform, three to cocaine, 277 to ether, nine to ether and gas, sixteen to gas, fourteen to gas and oxygen, five to gas, oxygen and ether, twenty-one to the administration of nitrous oxide, five to the administration of nitrous oxide and ether, nineteen to procaine and sixty to spinal anesthesia. How many deaths occurred in the practice of licensed physicians and how many occurred in the practice of unlicensed anesthetists? The evidence must be factual evidence. The profession has a long road to travel before it is going to adjust this matter either by creating a sentiment among physicians for the employment exclusively of licensed physicians or procuring the enactment of laws that will accomplish the same result and what is needed in the case is factual evidence rather than opinion.

DR A T MCCORMACK, Louisville, Ky. We realize in Kentucky that our law was defective but it accomplishes the purpose. The surgeon, when he employs a physician anesthetist is not responsible for anesthesia. When he employs a nurse anesthetist, unless she is licensed, he is. In that way we have accomplished our purpose.

DR B R KIRKLIN, Rochester, Minn. There is one thing that hasn't been mentioned and that is this proposed division of radiology into two parts, the technical and the professional, and allowing the hospital to employ the help and provide the service for technical work in radiology. That plan, it seems to me, is a bad move so far as radiology is concerned. Another idea in that plan is to allow any one to interpret certain types of radiologic observations, which is bad. It must be remembered that this plan was conceived to enable hospitals to sell group hospitalization insurance. In other words, it is purely commercial; it is a question of who is going to make the money out of radiology.

DR J P SIMONDS, Chicago. I am not surprised that Dr Woodward is disappointed in the outcome of this discussion because I think that in all probability, from his point of view, most of the discussers missed the point. So far as my own presentation was concerned it had nothing to do with the requirement by state law of licensure of pathologists. I was taking it for granted that the pathologist would see that it was to his advantage to possess a license to practice medicine without being required to get one by law. Dr McCormack, I believe mentioned the fact that there were not enough pathologists to go around. There are several reasons for this. There have been so many inroads into the practice of pathology by state boards of health or by various other lay or academic activities that there is not enough material left for any great number of pathologists to make a decent living. The inroads have not been made into the province of roentgenology and anesthetics by the same agencies to anything like the extent

that the inroads have been made into the field of pathology I know of one hospital which in one year, that was before 1929, made \$35,000 out of its laboratory. It paid its pathologist at that time \$2,000. It had enough technicians to make up another \$3,600. The materials used were economically bought and utilized, so that this particular hospital had a profit of somewhere in the neighborhood of \$20,000 from its laboratory. Whether you want to call that exploitation of pathologists and laboratory is a matter, I presume, of opinion.

DR F H McMECHAN, Rocky River, Ohio. Dr Woodward wants some figures. There are figures available that are striking. For instance the only time that the surgical patient is profitable to a hospital is the first week of that patient's stay in the hospital. If a hospital is operating on an overhead of less than \$3 and preferably \$2.50 a day, it may break even the second week of the patient's stay in the hospital, but after that the surgical patient is a dead loss to the institution. The consequence is that the surgical patient must receive services which accomplish a turnover within a period of two weeks unless the hospital is simply to go out of the community for its overhead and its deficits. Where does anesthesia come in in that economic situation? Let me quote figures from the gopher department of the University of California Hospital. The average turnover is six days. It is only the most complicated substernal types of goiter that remain until the seventh, eighth or ninth day and seldom does any patient in that department remain over nine days. At the Lahey Clinic in Boston, using exclusively medical anesthetists, and the Crotti Clinic at Columbus, Ohio, using exclusively medical anesthetists, 17,000 goiters and some 9,000 goiters, respectively, have been operated on with a death rate of a fraction of 1 per cent. Dr Chambers of Doncaster, England, works at the Brampton Hospital. Before Dr Chambers came to the United States and got our latest methods in gas anesthesia, the anesthetics were given by highly qualified medical anesthetists, but when Dr Chambers returned to Brampton Hospital and instituted gas oxygen almost exclusively he took a gross surgical death rate that had been standing in that hospital over a period of years between 4 and 5 per cent and in a four-year period reduced the gross surgical mortality to a fraction over 1 per cent, and the only change that had been made in the surgical service of the hospital was the introduction of Dr Chambers' services as an expert anesthetist and his introduction of gas oxygen anesthesia. Similarly at the North Middlesex Hospital in London, DeCaux, by expert anesthesia and our modern methods of anesthetics, reduced the turnover of patients in the institution from thirty days per patient to eighteen days. Now imagine the saving.

(To be continued)

The Dancing Manias—In searching the literature for ancestral forms of infectious diseases of the nervous system, one cannot overlook a curious chapter of human affliction—namely, that dealing with the dancing manias spoken of in medieval accounts variously as "St John's dance," "St Vitus's dance" and "Tarantism." These strange seizures, though not unheard of in earlier times, became common during and immediately after the dreadful miseries of the Black Death. For the most part, the dancing manias present none of the characteristics which we associate with epidemic infectious diseases of the nervous system. They seem, rather, like mass hysterias, brought on by terror and despair, in populations oppressed, famished and wretched to a degree almost unimaginable today. To the miseries of constant war, political and social disintegration there was added the dreadful affliction of inescapable, mysterious and deadly disease. Mankind stood helpless as though trapped in a world of terror and peril against which there was no defense. God and the devil were living conceptions to the men of those days, who covered under afflictions which they believed imposed by supernatural forces. For those who broke down under the strain there was no road of escape except to the inward refuge of mental derangement which under the circumstances of the times took the direction of religious fanaticism.—Zinsser, Hans. Rats, Lice and History. Boston, Little Brown & Co. 1935.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Personal—Dr Doyle W. Fulmer, Little Rock, has been appointed director of the Saline County Health Unit, succeeding Dr Cad A. Henry, resigned.—Dr Howard A. Dishongh has been named deputy coroner for Pulaski County.

Pediatric Society Organized—The Arkansas State Pediatric Association was organized at a meeting in Little Rock, March 6. In addition to pediatricians, physicians especially interested in the care of the child may enjoy the clinical privileges of the society through associate membership. The first annual meeting of the society was held April 15, during the meeting of the state medical society. Officers are Drs Morgan Smith, chairman, and Madeline A. M. Melson, Little Rock, secretary.

District Meetings—At a meeting of the Third Councilor District Medical Society in De Valls Bluff, April 5, speakers were Drs Russell A. Hennessey, Memphis, Tenn., on "Diagnosis and Treatment of Gonorrhea and Its Complications," Francis W. Carruthers, Little Rock, "Points in Treatment of Fractures of Interest to the General Practitioner," Dewell Gann Jr., Little Rock, "The Cancer Problem," Eugene M. Holder, Memphis, Tenn., "Signs and Symptoms of Acute Surgical Conditions in the Abdomen Usually First Seen by the General Practitioner," and Oliver C. Melson, Little Rock, "Considering the Possibilities in Diagnosis."—The Fifth Councilor District Medical Society was addressed at a meeting in Magnolia, April 9, by Drs Francis W. Carruthers on the fracture problem, George F. Jackson, cancer of the skin, and Royal J. Calcote, corneal ulcer, all speakers are from Little Rock.—Speakers at a joint meeting of the Sixth Councilor District Medical Society and the Tri County Clinical Society (Clark, Nevada and Hempstead) in Prescott, March 12, among others, were Drs Guy A. Caldwell, Shreveport, La., on "Errors in Treatment of Fractures of the Long Bones," Merlun J. Kilbury, Little Rock, "Streptococcal Infection and Septicemia," and Herman W. Hundling, Little Rock, "Cancer of the Large Bowel."

DISTRICT OF COLUMBIA

The Kober Lecture—Dr Laurence S. Otell, associate professor of radiology, Georgetown University School of Medicine, Washington, gave the Kober Lecture, March 28. His subject was "Thorium as a Diagnostic Agent." This lecture is given under the auspices of the Kober Foundation of the university.

Medical Bills in Congress—S. 2153, to provide for the prevention of blindness in infants in the District of Columbia, has passed the Senate. An amendment proposed by Senator Copeland, New York, was adopted which exempts from the operation of the act "persons treating human ailments by prayer or spiritual means as an exercise or enjoyment of religious freedom."

Society News—Dr Fred W. Rankin, Lexington, Ky., addressed the Washington Chapter of the Pan American Medical Association, February 10, on "Early Diagnosis and Treatment of Cancer of the Colon." A meeting was held, March 10, in honor of the late Col. Bailey K. Ashford.—Dr Thomas Milton Rivers of the Rockefeller Institute for Medical Research, New York, discussed filtrable viruses and virus diseases before a meeting of officers of the U. S. Navy Medical Department, March 3.

FLORIDA

Bills Introduced—S. 63 proposes to limit the sale and other distribution of appliances, drugs or medicinal preparations intended or having special utility for the prevention of venereal diseases, to persons licensed by the state board of health to distribute them. S. 190 proposes to authorize the sexual sterilization of idiot, imbecile, feeble-minded or epileptic inmates of state institutions. S. 255, to amend the law requiring physicians to register annually with the state board of health and to pay a fee of \$1, proposes that after a physician has once registered with the board and paid a fee of \$2 he need not reregister until such time as he changes his residence or the place in which he intends to carry on the practice of medicine. S. 331 proposes to authorize the board of county commissioners

of Columbia County to levy annually a tax not to exceed five mills on each dollar of taxable property, to defray the expense of medical and hospital treatment for indigent residents of the county

GEORGIA

State Medical Meeting at Atlanta—The Medical Association of Georgia will hold its annual meeting in Atlanta, May 7-10, under the presidency of Dr Clarence L Ayers, Toccoa. The scientific program will be presented by the following physicians

Michael J Egan Savannah On Fascia Repair in the Cure of Hernia
Frank H Boland, Atlanta Carcinoma of the Colon
Allen R Rozar Macon Pneumoperitoncum Following Operation for Hernia
Charles E Rushin Atlanta Treatment of Varicose Veins and Ulcers
Thomas P Goodwyn and Henry Walker Jernigan Atlanta The Fifth Lumbar Vertebra as a Cause of Low Back Pain
Lawson Thornton and James Calvin Sandison Atlanta Treatment of Fractures of the Hip (Neck of Femur) with Internal Fixation and Immediate Motion of the Joint
John W Brittingham, Augusta, Hypothyroid Heart Disease
Thomas F Sellers Atlanta Laboratory Aids in the Diagnosis of Typhoid Fever
Roy R Kracke and Francis P Parker Emory University Relation ship of Drugs to the Leukopenic State
Carl C Aven and Albert Worth Hobby Jr Atlanta Treatment of Acute Lobar Pneumonia
Russell H Oppenheimer Atlanta The Trend of Medical Education
Zachariah W Jackson Atlanta The Responsibility of the General Practitioner in Diseases of the Eye
Louis C Roughlin Atlanta Laryngeal Tuberculosis
David Henry Poer Atlanta Treatment of Thyroid Disorders
Daniel C Elkin Atlanta Appendicitis Factors Influencing the Mortality
Sam Brock Augusta Carotid Body Tumor
Ralph H Chaney Augusta Benign Fibroma of the Small Bowel
Job C Patterson Cuthbert Acute Ruptured Peptic Ulcer
Evans B Wood Atlanta Treatment of Syphilis in Pregnancy with the Report of Three Cases of Arsenical Encephalitis Complicating Such Treatment
Robert C Pendergrass Americus The Chronic Cough
Charles E. Hall Jr Atlanta Scientific Management of Anal Fissure
Olin S Cofer Atlanta Treatment of Complete Prolapse of Uterus by the Vaginal Route
William Perrin Nicolson Jr Atlanta Irradiation Versus Surgery in Breast Malignancies
James A Fountain, Macon Carcinoma of the Cervix

There will also be a symposium on pediatrics, presented by Georgia physicians. Dr Leavelly F Barker, professor emeritus of medicine, Johns Hopkins University School of Medicine, Baltimore, will deliver the Abner Weilborn Calhoun Lecture on "Treatment by the General Practitioner of the More Common Diseases of the Nervous System," and Reuben L Kahn, Sc D, director of laboratories University of Michigan Medical School, Ann Arbor, Mich., will speak on "Newer Concepts of Immunity and Allergy." On this occasion Dr Austin A Hayden, Chicago, will show a motion picture of the activities at the headquarters of the American Medical Association.

ILLINOIS

Bills Introduced—H 779 proposes to accord to physicians hospitals and nurses treating persons injured through the fault of others liens on all rights of action claims judgments, compromises or settlements accruing to the injured persons by reason of their injuries. H 780 proposes to enact a separate chiropractic practice act. The bill proposes to define chiropractic as the science of palpating and adjusting the articulation of the human spinal column by hand only. H 781 proposes to enact a new chiropractic practice act which, apparently, would enlarge the scope of a license to practice chiropractic. "A person," the bill states "practices chiropractic within the meaning of this act who offers or undertakes, by any means or method, to diagnose, recommend or prescribe for any ailment or supposed ailment of the human foot of another or who offers or undertakes the local, medical, mechanical or surgical treatment of any ailment or supposed ailment of the human foot of another including general manipulative massage, whether manual, mechanical or electrical, except amputation of the foot or toes or the use of anesthetics other than local, or the use of drugs or medicines other than local anesthetics." H 814 proposes to authorize the formation of corporations to operate nonprofit hospital services plan whereby hospital service may be provided by the said corporation or hospital with which it has a contract for such care to those persons who become subscribers to said plan under a contract which entitles each subscriber to certain hospital care. H 818 proposes to make it unlawful to engage in the business of manufacturing cosmetics medicines or drugs without first obtaining a license from the department of agriculture and paying a fee of \$2500. The department is to investigate the contents and ingredients of the cosmetics, drugs or medicines manufactured by the person applying for a license and, if it finds that the articles are adulterated or that any state-

ment in the application is false or misleading or that the brand, name or any label or advertisement of the product gives a false indication of origin, character, composition or place of manufacture, it may refuse to license the applicant

Chicago

Society News—Drs Claude F Dixon, Rochester, Minn., and Fuller Albright, Boston, addressed the Chicago Medical Society at its final meeting for this season, April 24, on "Rectal Cancer Management and Prognosis" and "Hyperparathyroidism," respectively—Speakers at a meeting of the Chicago Society of Internal Medicine April 22, were Drs Margaret M H Kunde, on "Blood Studies on Acetone, Glucose and Glutathione" William A Brams and Otto Saphir, "Adequate Myocardial Nutrition in Occlusion of Both Coronary Arteries" and Nathan S Davis III, "The Incidence of Diseases of the Blood Vessels"—Drs Herbert E Landes and Patrick H McNulty, among others, addressed the Chicago Urological Society, April 25, on "Malignant Tumors of the Testis" and "Carbuncle of the Kidney," respectively

IOWA

Uniform Plan of Medical Relief—The organization of the Iowa State Medical Society will be used in a new uniform plan for medical relief to be launched in Iowa, it is announced. It is proposed to use the eleven districts of the state medical association, which are composed of nine counties each, to coordinate the work. The aim is to eliminate the necessity for small county groups to negotiate with local officials for irregular and frequently unsatisfactory arrangements to care for the poor. Investigation of cases will be made by social workers, who will decide whether a physician is necessary. The family physician will receive an order for medical care and will be paid according to a fee schedule drawn up by the state medical society. Since the plan is designed for counties receiving federal aid it is pointed out that it need not be adopted by those capable of handling their own medical relief situations. Dr Thomas C Denny, recently appointed medical referee in handling emergency relief in Iowa, is chairman of the state organization. There is an advisory group of physicians, and consultants for hospitals and pharmacists. The councilors of the district medical societies will have regional supervision. The county organizations will include the medical relief committee, consisting of the county deputy councilor as chairman, the president and secretary of the county medical society, or, when these titles overlap, a third to be selected by the other two. The committee will act in close cooperation with the county director of relief, who is to authorize all relief service. Heretofore Iowa relief has been administered under five widely different methods with as many minor variations as there are counties

MARYLAND

Conference on Vitamins—The department of chemistry of Johns Hopkins University Baltimore, announces that its fifth research conference will be held at Gibson Island, June 24-July 12 under the general title of organic chemistry. One week will be given over to a discussion of vitamins by the following speakers Elmer V McCollum, Sc D Baltimore, Robert R Williams, Roselle N J Charles G King, Ph D Pittsburgh Charles E Bills, Ph D, Evansville, Ind, and Henry C Sherman, Sc D New York. Further information may be secured from Neil E Gordon, Ph D, Department of Chemistry, Johns Hopkins University

MASSACHUSETTS

Public Health Council Created—Springfield's health department will now be supervised by a public health council instead of the former board of health, newspapers reported February 8. Announcement was also made of the appointment of Dr Lawrence Jackson Smith, Apponaug, R I as health officer. Under the new arrangement, all health work in Springfield will be coordinated under the public health council of which Dr Frank H Baehr is chairman. Other members of the council include A C Rock, DDS, and Dr Eoline B C Dubois

Society News—The New England Health Education Association will hold its tenth annual conference, May 31-June 1, at the Massachusetts Institute of Technology, Cambridge, speakers will include Dr Harold C Stuart, Boston, on nutrition—Dr Philip Solomon, among others, addressed a recent meeting of the Boston Society of Psychiatry and Neurology on "The Psychogalvanic Reflex—Application in Psychiatry and Neurology."—Dr Merrill Moore discussed syphilis of the nervous system before the Boston Medical History Club, April 15

MICHIGAN

Nutrition Project.—The state emergency welfare relief commission, the Children's Fund of Michigan and the state department of health are cooperating in a program to prevent an increase in scurvy and other dietary deficiency diseases among infants and young children and to assist in making necessary medical care available for needy prospective mothers. The Michigan branch of the American Academy of Pediatrics is acting in an advisory capacity. Members serve as consultants to work with the county medical societies and nurses in their respective districts. The project will continue over a period of six months. According to the state medical journal, the work is based on home calls to families on relief or near the borderline in which there are prospective mothers or young children. The expectant mother receives suggestions and, in families with infants, special attention is paid to dietary supervision to guard against scurvy and rickets. The project was begun at the suggestion of Dr Thomas B Cooley, Detroit, president of the American Academy of Pediatrics.

Ballin Memorial Lectures.—The second series of the Dr Max Ballin Memorial Lectures opened April 11, at the North End Community Clinic Detroit with a discussion by Dr Solomon Strouse Chicago on 'Obesity and Malnutrition, Their Causes and Management.' Drs Plinn F Morse and Harold C Mack spoke April 25 on 'Parathyroid and Adrenal Disturbances' and 'Gonadal Disturbances in the Female.' Other speakers in the series will be:

- Dr Russell L Haden Cleveland Arthritis in Relation to Endocrinology and Metabolism May 2
- Dr Robert C Moehlig Pituitary Disturbances May 9
- Dr Israel J Zimmerman Endocrine Studies in Female Sterility May 9
- Drs Hugo A Freund and Harry C Saltzstein Thyroid Disturbances May 16
- Icie Macy director research laboratory Children's Fund of Michigan Mineral Metabolism and Its Practical Applications May 23
- Oliver Kamin, Ph.D. scientific director research laboratory Parke Davis & Co. Water Metabolism and Its Practical Application May 23
- Dr Israel M Rabinowitch Montreal Que. Newer Views in the Diagnosis and Treatment of Diabetes Mellitus June 6

MINNESOTA

Bill Enacted.—H 212 has been enacted as chap 165, Laws 1935, requiring every physician or the governing authorities of every hospital, on treating persons suffering from gunshot or knife wounds, to report the facts immediately to the proper police officials.

Society News.—Speakers before the Minnesota Academy of Ophthalmology and Otolaryngology in Minneapolis, February 8, included Drs James F Brusegard Red Wing, on 'Ocular Complications of Rosacea', Alvin Glenwood Athens, Duluth 'A Method and Instrument for Localization of Retinal and Choroidal Lesions', and Henry L Williams Jr, Rochester, 'End Results in 200 Cases of Chronic Maxillary Sinusitis Operation by the Intranasal Route with the Application of the Surgical Principles of Kuster.' Dr Charles N Spratt, Minneapolis, reported a case of retinal detachment.—Dr Herman L Kretschmer, Chicago discussed 'Diagnostic Problems in Urology' before the Hennepin County Medical Society in Minneapolis, recently.

MISSOURI

Committee to Study Smoke Problem.—A subcommittee of the committee on health and public instruction of the St. Louis Medical Society has been authorized to make a study of the smoke problem in the city. A similar study will be carried out by a committee appointed by the mayor, it was reported.

Health Commissioner of Kansas City Appointed.—Dr Edwin Henry Schorer Kansas City, has been selected as health commissioner of Kansas City, succeeding the late Dr Jabez N Jackson. Dr Schorer graduated from Johns Hopkins University School of Medicine in 1906 and received the degree of doctor of public health from Harvard University in 1912. He served as a fellow at the Rockefeller Institute for Medical Research, New York and was associate professor of parasitology and hygiene at the University of Missouri School of Medicine and later associate professor of pathology and bacteriology at the University of Kansas School of Medicine. During the World War he was chief of the laboratory division of the base hospital at Fort Riley and director of the laboratory division and officer in charge of the laboratory at the Port of Embarkation at Hoboken, N. J.

Personal.—Dr David P Barr Busch professor of medicine, Washington University School of Medicine, St. Louis recently returned from Australia where he lectured at the invitation

of the Melbourne Postgraduate Association. According to *Science*, this association conducts for the physicians of the state of Victoria graduate instruction. During the past decade, it has been the custom to invite each second year a physician from England or the United States to give a series of stated lectures.—Dr Edwin L Sheahan Clayton, has been appointed health commissioner of St. Louis County to succeed Dr Louis C Obrock. Dr Sheahan will continue as superintendent of the county hospital in Clayton, a position to which he was appointed January 1.—Dr Arthur E Hertzler was made the first honorary member of the Kansas City Obstetrical and Gynecological Society, March 28. He addressed the society that evening on 'Lesions of the Uterus.'

NEBRASKA

Bill Passed.—H 587 has passed the house, proposing to prohibit the retail distribution or sale of barbitol or other hypnotic or somnifacient drugs, except on the prescription of a licensed physician, dentist or veterinarian.

NEW HAMPSHIRE

State Medical Meeting at Manchester.—The one hundred and forty-fourth annual meeting of the New Hampshire Medical Society will be held in Manchester, with headquarters at the Hotel Carpenter May 7-8. A symposium on obstetrics will be presented by the following Boston physicians: Drs. Marion F Cades, Frederick C Irving, Foster S Kellogg and Richard S Eustis. Other guest speakers will be:

- Dr James S McEster Birmingham Ala. President Elect of the American Medical Association Nutritive Failures as a Clinical Problem
- Dr Crover C Penberthy Detroit Treatment of Burns
- Dr Nathan B Van Etten New York Medical Economics of 1935
- Dr Harold E McMahon Boston Bright's Disease
- Dr Harry E Mock Chicago Treatment of Skull Fractures

New Hampshire physicians on the program will be: Dr Chester F McGill Portsmouth Congenital Pyloric Obstruction. Dr Fred E Clow Wolfeboro Constipation. Frank H Connell Ph.D. Hanover Amebiasis in a Rural Community. Drs John A Coyle and Leslie K. Seamore Hanover Bronchoscopy. A gold medal will be presented to Dr Edward H French, Quincy, Mass., and Potter Place, in recognition of his fifty years of membership in the society. The following physicians who have practiced medicine fifty years will be introduced: Drs Louis W Flanders, Dover; Frank E Kittredge Nashua; Frank S Lovering Moultonboro; William S Manuel Portsmouth; Edward E Twombly, Colebrook, and Ellen A Wallace, Manchester. Dr Frederic P Lord, Hanover, is president.

NEW JERSEY

State Medical Meeting at Atlantic City.—The one hundred and sixty-ninth annual meeting of the Medical Society of New Jersey will be held in Atlantic City, April 30 May 2. The house of delegates will meet April 30. General scientific meetings will be held May 1, and sectional meetings May 2. Speakers at the general meetings will be:

- Dr Homer I Silvers Atlantic City Lymphogranuloma Inguinale as a Causative Factor in Rectal Strictures
- Dr George W Crite Cleveland Polyglandular Disease
- Dr David D Berlin Boston Treatment of Chronic Heart Disease by Total Thyroidectomy
- Dr Benjamin Franklin Buzby Camden Acute Osteomyelitis
- Dr Paul Dudley White Boston Coronary Disease in Young People
- Dr Robert A Mackenzie Ashbury Park Causes and Management of Premature Labor
- Dr Earl LeRoy Wood Newark Functional Rest of the Nose in the Treatment of Upper Respiratory Infections
- Dr James B Herrick Chicago Coronary Disease.

Features of the sectional meetings will include a symposium on acute poliomyelitis by Drs John A Kolmer, Philadelphia and William H Park and Maurice Brodie, New York. Other speakers from outside the state include:

- Dr Sylvan E Moolten New York Histologic and Pathologic Diagnosis of Primary Carcinoma of the Lung (symposium)
- Dr Frederic Maurice McPhedran Philadelphia Roentgen Diagnosis of Childhood Tuberculosis (symposium)
- Dr Emanuel Lihman New York Diagnostic Studies in Pain with Reference to Abdominal Disorders
- Dr Samuel J Kopetzky New York Influence of Bone Structure on the Purulent Lesions of the Temporal Bone
- Dr Algernon B Reese New York Operative Treatment of Squint

The president's banquet and ball will be held at Chalfonte Haddon Hall, Wednesday evening when Dr Lancelot Ely Somerville, will give his presidential address and Dr Marcus W Newcomb, Browns Mills, president-elect, his inaugural address. The woman's auxiliary will also meet during the three days under the presidency of Mrs Arthur J Casselman Camden. The auxiliary will have charge of the annual art and hobby exhibit showing the leisure time accomplishments of members and their families.

NEW MEXICO

Appointments to Medical Board—Gov Clyde Tingley has appointed the following physicians to the state board of medical examiners for four year terms Drs James M Doughty, Tucumcari, Frank H Johnson, Carrizozo, and Tobias Espinosa, Espanola They succeed Drs Robert E McBride, Las Cruces, Percy G Cornish Jr, Albuquerque, and Robert L Bradley, Roswell Dr Frederick F Doepp, Carlsbad is president, Dr Johnson, vice president, and Dr Earle L Ward, Santa Fe, secretary

Society News—The New Mexico Public Health Association will meet in Santa Fe, April 30-May 1 in conjunction with the southwestern division of the American Association for the Advancement of Science—Dr Esmond R Long, Philadelphia conducted a clinic on the use of tuberculin at the U S Indian School, Santa Fe, March 3—Dr Arthur J Wheeler, Albuquerque, conducted a discussion of Compression Therapy of Pulmonary Tuberculosis at a recent meeting of the Southwest Indian Service Medical Society in Albuquerque, among other speakers Wives of the members of the society recently formed an auxiliary to meet at the same time as the medical society—Dr Walter A Gekler addressed the Bernalillo County Medical Society, Albuquerque March 6, on The Economic Situation of the Physician and Dr Charles Howe Eller, then county health officer, methods of controlling epidemic meningitis Dr Walter I Werner addressed the society recently on childhood tuberculosis

Health in New Mexico—A report of the Bureau of Public Health of New Mexico for the two years 1933-1934 discusses the health problems that face the state During the biennium a state wide health survey was made by Carl Buck, Dr PH of the staff of the American Public Health Association, with funds supplied by the New Mexico Tuberculosis Association and the State Health Protection Fund. The report of this survey showed that there are 10,000 cases of tuberculosis in the state and an auxiliary study by the American Social Hygiene Association listed 21,000 cases of syphilis Of the latter, it is said that only 1,000 are under a physician's care Typhoid is a serious problem, 355 cases having been reported in 1933 and 358 in the first eleven months of 1934 In 1934, 218 cases of malaria were reported several drainage control projects for control of malaria are now in progress Diphtheria was found to be decreasing as a result of immunization campaigns and public education Six counties have full time health officers, and the remaining twenty-five have part time officers All but two counties had public health nurses at the time of the report The public health laboratory examined 80,116 specimens during the two years, as compared with 49,052 in the preceding biennium Much of the increase was in connection with the health survey and the Civilian Conservation Corps camps A summary of vital statistics shows that the death rate has decreased from 16 per thousand of population in 1930 to 13.2 in 1933 The infant death rate in 1933 was 133.4, an increase over that of the preceding year, but less than the rates for 1929 and 1930 The birth rate also decreased from 30.2 in 1930 to 28.2 in 1933

NEW YORK

New Health District—A new health district has been established in Tompkins County, with headquarters at Ithaca, as a cooperative project of the U S Public Health Service the state department of health and the Tompkins County Development Association Dr Vivian A Van Volkenburgh, formerly associate in epidemiology at Johns Hopkins University School of Hygiene and Public Health Baltimore is head of the staff, which includes a sanitary engineer a supervising nurse and four public health nurses Local boards of health and local health officers will continue their present activities, according to *Health News* The new district is the first to be developed under the plan for federal aid to rural areas for health work The Tompkins County Medical Society gave its approval at a meeting January 23 at which Dr Thomas Parran Jr, state health officer, explained the proposed plan

New York City

Salmon Memorial Lectures—Dr William Alanson White professor of nervous and mental diseases at George Washington University School of Medicine and superintendent of St Elizabeth's Hospital, Washington, D C delivered the first of the third series of Thomas William Salmon Memorial Lectures at the New York Academy of Medicine, April 12 on "Psychiatry as a Medical Specialty", the second April 19, on "Social Significance of Psychiatry" and the third April 26, on "General Implications of Psychiatric Thought"

Cornell Alumni Meeting—The annual "Spring Day" of the Cornell University Medical College Alumni will be held May 2 Lectures, clinics and demonstrations will be held during the day, with all departments of the college and of New York Hospital taking part Alumni will be guests of the governors of New York Hospital at luncheon In the evening there will be a dinner at the Hotel Biltmore, at which the speakers will be Dr Livingston Farrand, president of Cornell Dr James Ewing professor of oncology in the medical college, and Judge William F Bleakley, president of the Cornell University Law Association

Mayor Presents Certificates for Public Service—More than 1,600 persons recently attended a dinner at the Waldorf-Astoria in honor of twelve physicians who had served on the staff of the Jewish Hospital of Brooklyn for twenty-five years or more The guests of honor were Drs Simon R Blatter, Adolph Bonner, Isaac D Kruskal, Max Lederer, John Linder, William Linder, Joshua Ronsheim, Simon Rothenberg, Leo S Schwartz, Herman Shann, Milton G Wasch and Benjamin E Wolfort Among others present was Mayor La Guardia who in expressing his desire to recognize officially "real public service," in contradistinction to "occasional or accidental public service" stated that in the near future he would present to these twelve physicians "certificates for distinguished and exceptional public service" The mayor came to the hospital February 26 and presented to the twelve physicians certificates which he had signed He thus inaugurated in New York City the certificate for public service Other speakers at the ceremony were Borough President Raymond V Ingersoll of Brooklyn, Joseph Baker and Justice Harry E Lewis president and vice president of the hospital, respectively, and Justice Mitchell May, president of the Brooklyn Federation of Jewish Charities Brooklyn The Jewish Hospital is the largest nonsectarian hospital in Brooklyn and, since opening in 1906, has admitted about 175,000 patients

NORTH CAROLINA

Bill Introduced—H 1133 proposes to exempt from taxation all general hospitals which conduct a training school for nurses or which furnish the use of their facilities to indigent patients

Society Disapproves of Socialized Medicine—At a meeting in Greenville, March 14, the Second District Medical Society unanimously endorsed the action of the House of Delegates of the American Medical Association at its special meeting in Chicago, February 15-16 and condemned all forms of socialized medicine Speakers at the meeting were Drs Paul P McCain Sanatorium, president of the Medical Society of North Carolina, on "Problems of the Physician" Louis B McBrayer, Southern Pines, secretary of the state society, "Medical Economics", Benjamin J Lawrence, Raleigh, "Traumatic Surgery," and Charles H Ashford, New Bern, "Trigeminal Neuralgia"

OHIO

Seventy-Five Years of Practice—Dr William Eberle Thompson, Bethel, celebrated the completion of seventy-five years of medical practice, newspapers reported recently He was graduated from the Cincinnati College of Medicine, since amalgamated with other schools to form the University of Cincinnati College of Medicine, in 1860 He will celebrate his one hundredth birthday July 6 Dr Thompson has spent his entire life in Bethel

Concert by Physicians' Orchestra—The Doctors Symphony Orchestra of Akron gave its fifty-third concert, April 11, at the People's Hospital The orchestra, founded in 1926 is under the direction of Dr Alexander S McCormick It has thirty-seven members, of whom fourteen are physicians Among the musicians are former members of the symphony orchestras of Chicago, Toronto, Cleveland and London, as well as of Sousa's Band and various military bands of the United States and Canada

Northern Tri-State Meeting—The annual meeting of the Northern Tri-State Medical Association (Ohio, Indiana and Michigan) was held in Lima April 9 Among speakers were

Dr John Walker Moore, Louisville Ky Studies on the Circulation in Cases of Hypertension
Dr Willard Bartlett, St Louis Lessons Derived from a Five Year Mortality Study
Dr Alan G Brown, Toronto Ont Errors in Diagnosis and Therapy in Pediatrics
Dr Ralph A Kinsella, St Louis Chronic Arthritis

At the banquet in the evening at the Barr Hotel speakers were Drs Max Cutler, Chicago, on "The Present Position of Radiation in the Treatment of Cancer," and Emil Novak, Baltimore Recent Advances in Gynecologic Endocrinology Dr

Edward P. Gillette, Toledo, was elected president. Dr. Glenn E. Jones, Lima, vice president, and Dr. Jon N. Kelly, Laporte, Ind., secretary.

OKLAHOMA

Bills Introduced—S 281 proposes to authorize the court to require a plaintiff in an action for damages for personal injuries to submit to physical examination, provided the defendant pays the examining physicians' fees and the necessary laboratory and x-ray charges, and other expenses in connection with such examination. H 478 proposes to require the county excise board of each county to levy a tax of not to exceed one-eighth mill of each dollar of assessed value of property subject to taxation to create a hospitalization fund out of which the county is to supply necessary antepartum and postpartum care for indigent women.

PENNSYLVANIA

Bills Introduced—S 848 proposes to authorize the sexual sterilization of inmates of institutions for the mentally defective. H 2065 proposes to accord to every charitable hospital treating persons injured through the fault of others, liens on all rights of action, claims, judgments, settlements or compromises accruing to the injured persons by reason of their injuries. The proposed lien, however, cannot exceed 50 per cent of any recovery had by the patient.

Philadelphia

Death of Professor Duane—William Duane, Ph.D., emeritus professor of biophysics, Harvard University, and a pioneer in the development of the fundamental principles in the use of x-rays and radium, died March 7 at his home, aged 63. Professor Duane, a native of Philadelphia and a descendant of Benjamin Franklin, was graduated in 1892 from the University of Pennsylvania and in 1893 from Harvard, taking the degree of doctor of philosophy at the University of Berlin in 1897. At the invitation of the late Pierre and Marie Curie, Dr. Duane went to Paris in 1907 and spent five years collaborating with them in their research on radium. In 1913 he returned to become assistant professor of physics at Harvard, and in 1917 the chair of biophysics was created for him. He divided his time between the physics laboratory at Harvard and Collis P. Huntington Memorial Hospital, carrying out research under direction of the cancer commission of the university until his retirement in 1934 because of declining health. Dr. Duane is credited with the following achievements of medical importance: design and construction of an automatic apparatus for drawing off radon gas from radium into "seeds" for therapeutic use; design and early use of constant potential high voltage x-ray power plant utilizing high frequency generators; pioneer work on the roentgen, the unit by which x-ray dosage is measured; and development of therapeutic use of thorium and uranium target x-ray tubes. Among other organizations, Dr. Duane was a member of the American Roentgen Ray Society, a fellow of the American College of Radiology and honorary member of the Radiological Society of North America, and at one time served as president of the American Society for Cancer Research. Among many honors he received were honorary degrees from the Universities of Pennsylvania and Colorado, the John Scott Medal of the Franklin Institute of Philadelphia, the Comstock Prize of the National Academy of Sciences, and the first Leonard Medal of the American Roentgen Ray Society.

Pittsburgh

Society News—A symposium on pneumoconiosis was presented before the Allegheny County Medical Society, April 16, by Drs. Lucy Schnurer, Wesley L. Allison, Charles M. Boucek and Samuel R. Haythorn. In addition Dr. Howard A. Power spoke on 'Trial Labor', Ernest W. Willetts, "Heredity of Blood Groups" and John A. Hagemann, "Political Paternalism—A Menace to Medicine." The public relations auxiliary committee on dispensary practices and policies has recently placed in all dispensaries in the county placards informing patients that the physicians' time and service are given gratuitously.

RHODE ISLAND

Committee on Economics Appointed—The president of the Rhode Island Medical Society, Dr. Albert H. Miller, Providence, recently appointed a committee on economics to consider problems of medical economics as they affect the society to cooperate with similar committees of other state societies and to act as an interim committee on legislation. Members are Drs. James A. McCann, Providence, temporary chairman; Norman S. Garrison, Woonsocket; John Helfrich, Westerly,

Charles L. Farrell and Charles H. Holt, Pawtucket; William A. Mahoney, Anthony Corvase, Herbert E. Harris and Charles F. Gormly, Providence.

SOUTH CAROLINA

Tribute to Dr. McLeod—More than 100 friends of Dr. Frank H. McLeod, Florence, entertained him at dinner, February 26, in honor of his sixty-seventh birthday. The late Dr. William Eggleston, Hartsville, president of the South Carolina Medical Association, was toastmaster, and speakers included Drs. James W. Jervey, Greenville, Robert Wilson, Charleston, Charles R. May, Bennettsville, Charles F. Williams, Columbia, and Marion R. Mobley, Florence. A gold watch was presented to Dr. McLeod by physicians of the Pee Dee section and a silver pitcher by friends of the Columbia Medical Society. Dr. McLeod was president of the state medical association in 1917 and was at one time editor of the *Journal of the Medical Association of South Carolina*.

TENNESSEE

Bills Introduced—S 964, to amend the medical practice act, proposes (1) to eliminate the provision in the present law requiring that the board of medical examiners consist of "four representatives from the regular school, one from the eclectic and one from the homeopathic school of medicine", (2) to require members of the board to have "graduated from an acceptable or class A medical school classified as such by the Council on Medical Education and Hospitals," and (3) to require the governor to appoint the members of the board from a list of names submitted by the Tennessee State Medical Association. H 1339 proposes to prohibit the sale or distribution, except by licensed druggists or by licensed physicians of any 'appliance drug or medicinal preparation intended or having special utility for the prevention of conception, and/or of venereal diseases'.

TEXAS

Bill Introduced—H 786 proposes to authorize the establishment of a state tuberculosis sanatorium for Negroes.

The Largest Mottled Enamel Area—A survey recently completed by the U. S. Public Health Service and the Texas State Department of Health offers evidence that the Panhandle-West Texas district is the largest mottled enamel area in the United States. A less exhaustive study in the east central part of the state revealed another endemic area, the extent of which was not determined. Fifty-three communities in thirty-seven counties in the western area were surveyed by examination of the teeth of school children, usually of the fourth, fifth and sixth grades. A history of the water supply used was taken and the degree of severity of the condition noted in accordance with a classification previously worked out, varying from 'questionable' to 'severe.' Communities were classified according to the percentage of each degree of severity. Only children who had been born in the community and had always used the municipal water supply were counted in the determination of the community's mottled enamel index. Samples of the water supply were taken and were being examined for fluorides in the laboratories of the state health department at the time of the report (*Public Health Reports*, March 29, p. 424). Of the fifty-three towns surveyed in West Texas, only six could be classified as "borderline" or "negative." In Lubbock, a town of 20,000, the teeth of all the children examined (176) showed mottled enamel, in Plainview seventy-six out of seventy-eight showed it in some degree in Amarillo, the largest city of the area, only five out of 168 children had normal teeth. The fact that the water supplies of such large towns contain the causative factor in sufficient concentration to produce such a high incidence of mottled enamel has developed an acute public health problem, the investigators concluded. In the east central area only thirteen communities were surveyed, but of these two were classified as "borderline" and none as "negative."

VERMONT

Bill Enacted—S 61 has become a law, prohibiting the sale, distribution or possession of cigarettes, cigars or tobacco, or other commodities intended for smoking, containing cannabis indica.

HAWAII

Personal—A luncheon was given recently by the Honolulu County Medical Society in honor of Drs. John Fraser, Edinburgh, Scotland; Melvin S. Henderson and Donald C. Balfour, Rochester, Minn.; and Dean D. Lewis, Baltimore.

GENERAL

Society News—The International Hospital Congress, originally scheduled to be held in Rome, May 5-12, has been postponed to May 19-26.—The Association for the Study of Allergy will hold its annual meeting at the Hotel Traymore, Atlantic City, June 10-11.

Change in Plans of Pan American Cruise—Dates for the cruise of the Pan American Medical Association to Brazil have been changed from July 18-August 28 to June 29-August 1, because of the fact that the S S *Columbia* originally chartered for the trip, has been withdrawn from cruise service. Arrangements have been made to charter the *Queen of Bermuda*.

American Students in Scottish Schools—A report from the secretary of the Association of American Medical Colleges shows that in the School of Medicine of the Royal Colleges Edinburgh, Scotland, there are twenty-six American students in the first year class during the current session. Of these twenty-six there are only three who had not made application to some school in the United States or Canada during the years 1932-1933 and 1934. Twenty-three made a total of 412 such applications, no one of which was accepted by any recognized school of medicine. One applicant was accepted by the Eclectic Medical College of Cincinnati.

Changes in Status of Licensure—The Oklahoma State Board of Medical Examiners reports the following action:

Dr. William Flournoy Griffin, Watonga, license restored after a year's suspension.

The New Jersey State Board of Medical Examiners reports the following revocations:

Malcolm Cameron Rose, formerly of New York, license revoked for violation of the narcotic laws Dec. 19, 1934. His New York license was also revoked in 1934.

Sam Roos Lustberg, formerly of Passaic, license revoked Dec. 19, 1934 for conviction of the crime of conspiracy.

Harry F. W. Petters, whose last known address was Englewood, license revoked February 27 because he failed to submit evidence of having become a citizen within the time specified in the New Jersey statute.

Thomas S. Sheppard, Millville, license revoked March 27 for the practice of criminal abortion.

Secretary Kingsbury Resigns from Milbank Fund—John A. Kingsbury, secretary of the Milbank Memorial Fund, New York, since 1922, has resigned because of "differences of opinion as to policy," according to an announcement made by the board of directors after their annual meeting, April 19. According to the New York Times, April 20, it was said at the offices of the Milbank fund that nothing would be added to the formal announcement. Mr. Kingsbury's secretary reported that he was away for the week-end. The statement made after the annual meeting of the board of directors follows: "Following the meeting Mr. Milbank announced that John A. Kingsbury, secretary of the fund since 1922, had severed his connection with the fund owing to differences of opinion as to policy. At Mr. Kingsbury's request, his name was not presented for reelection as director or as secretary."

Artificial Fever Conference at Dayton, May 2—The Fifth Annual Fever Conference for physicians and others interested in the production of fever by physical methods and its use in the treatment of disease will be held in Dayton, Ohio, May 2-3, at the Engineers' Club Hotel headquarters will be the Hotel Van Cleve. About forty papers are listed on the preliminary program. Among them are the following:

Dr. George R. Duncan, Oak Terrace, Minn., Report on Hyperpyrexia in Tuberculosis as Carried Out at Glen Lake Sanatorium.

Drs. Stafford L. Warren and Charles M. Carpenter and Ruth A. Boak, Ph.D., Rochester, N. Y., Basic Principles for the Cure of Gonococcal Infections by a Single Fever Treatment.

Dr. Philip S. Hensch, Rochester, Minn., Results of Fever Therapy for Gonorrheal Arthritis, Chronic Infectious (Atrophic) Arthritis and Other Forms of Rheumatism.

Drs. William Bierman and Harry Vesell, New York, Electrocardiographic Studies During Hyperpyrexia.

Dr. Howard P. Douth, Detroit, A Case of Osteogenic Sarcoma Treated with Fever Therapy and X-Ray Therapy.

Dr. Carl P. Huber, Ann Arbor, Mich., Results of Fever Therapy in Pelvic Inflammatory Disease.

Dr. Ralph H. Kuhns, Chicago, Present Status of Fever Therapy for Dementia Paralytica in the State Hospitals of Illinois.

Dr. Frank H. Krusen, Philadelphia, Studies of Blood Picture Before and After Fever Therapy.

Dr. Walter M. Simpson, Dayton, Report of Fever Therapy Research at Miami Valley Hospital.

Medical Bills in Congress—Bills Introduced. S. J. Res. 101, introduced by Senator Smith, South Carolina, proposes to amend the Emergency Relief Appropriation Act of 1935 to authorize grants to community hospitals. S. 2598, introduced by Senator Johnson, California, and H. R. 7635 introduced by Delegate Dimond, Alaska, propose to extend the benefits of the United States Public Health Service to certain fishermen. S. 2584, introduced by Senator Lewis, Illinois, proposes to amend the act entitled "An Act to recognize the high public service rendered by Major Walter Reed and those associated

with him in the discovery of the cause and means of transmission of yellow fever," by including therein the name of Gustaf E. Lambert, S. 2625, introduced by Senator Schwellessbach, Washington, proposes to extend the facilities of the Public Health Service to seamen on government vessels not in the military or naval establishments. H. J. Res. 245, introduced by Representative Greenway, Arizona, proposes to erect additions to the existing Veterans' Administration facilities at Tucson and Whipple, Ariz. H. R. 7320, introduced by Representative Johnson, West Virginia, proposes to erect an addition to the Veterans' Administration facility at Huntington, W. Va. H. R. 7326, introduced by Representative Granfield, Massachusetts, proposes to erect an addition to the existing Veterans' Administration facility at Northampton, Mass. H. R. 7377, introduced by Representative Lloyd, Washington, proposes to erect an addition to the existing Veterans' Administration facility at American Lake, Wash. H. R. 7502, introduced by Representative Eaton, New Jersey, proposes to erect an addition to the existing Veterans' Administration facility at Lyons, N. J. H. R. 7507, introduced by Representative Hill, Alabama, proposes to extend the benefits of existing veterans' laws and regulations to officers and enlisted men of the Army, Navy, Marine Corps and Coast Guard who suffer injury, disease or death while on authorized leave of absence or furlough, and to the dependents of such officers and enlisted men. H. R. 7508, introduced by Representative Citron, Connecticut, provides that all laws in effect on March 19, 1933, granting pensions to veterans of the Spanish-American War, including the Boxer Rebellion and the Philippine Insurrection, their widows and dependents be reenacted. H. R. 7522, introduced (by request) by Representative Darden, Virginia, proposes to erect a veterans' hospital in Virginia for Negro veterans. H. R. 7565, introduced by Representative Knutson, Minnesota, proposes to erect an addition to the existing Veterans' Administration facility at St. Cloud, Minn. H. R. 7618, introduced by Representative McGroarty, California, proposes to erect an addition to the existing Veterans' Administration facility at San Fernando, Calif. H. R. 7628, introduced by Representative Short, Missouri, proposes to erect a veterans' hospital in Missouri. H. R. 7630, introduced by Representative Ludlow, Indiana, proposes to erect an addition to the existing Veterans' Administration facility at Indianapolis. H. R. 7631, introduced by Representative Jones, Texas, proposes to authorize the erection of a veterans' hospital in the Panhandle section of Texas. *Change in Status*. H. R. 7260, the Doughton social security bill, has passed the House.

CANADA

University News—Dr. Claud R. G. Forrester, Chicago, addressed students of the University of Western Ontario, London, April 11, on "Reduction of Fractures under Local Anesthesia with Ambulatory Treatment."

Society News—Dr. Edward Murray Blair addressed the Vancouver Medical Association, Vancouver, February 5, on "Physiologic Observations in Obstetrics."—Dr. Walter T. Connell, Kingston, Ont., addressed the Academy of Medicine of Toronto, March 5, on "Clinical Experience with Acute Encephalitis and Its After-Effects."

Balfour Lecture—Dr. Everts A. Graham, Bixby professor of surgery, Washington University School of Medicine, St. Louis, delivered the eighth annual lecture under the Donald C. Balfour Lectureship at the University of Toronto Faculty of Medicine, April 5, the one hundred and eighth anniversary of the birth of Lord Lister. His subject was "Primary Carcinoma of the Lung or Bronchus."

Professor Appointed—Dr. Andrew Hunter of the University of Glasgow, Scotland, has been appointed professor of pathologic chemistry at the University of Toronto, succeeding the late Prof. Victor J. Harding, D.Sc. Dr. Hunter was at one time assistant professor of biochemistry at Cornell University and later biochemist of the U. S. Public Health Service. In 1915 he was made professor of pathologic chemistry at Toronto and in 1919 professor of biochemistry, leaving in 1928 to become Gardiner professor of physiological chemistry at the University of Glasgow. The appointment is effective next July.

Personal—Dr. Geoffrey N. Paterson-Smyth, Montreal, has been appointed chief neurologist to the Women's General Hospital, Westmount, Que.—Dr. Louis Arthur Lessard, superintendent of Hôpital Notre-Dame, Montreal, has been appointed inspector general of all institutions in Quebec that come under the Public Charities' Act, a new position created with a view to limiting the stay of patients in these institutions as much as possible.—Dr. Albert Grant Fleming, Montreal, has been appointed secretary to the health insurance

committee of the British Columbia College of Physicians and Surgeons—Earl J. King, Ph.D., assistant professor of medical research, University of Toronto Faculty of Medicine, has been appointed reader in pathologic chemistry at the British Post-Graduate Medical School—Dr. Frederick E. Lawlor, medical superintendent of Nova Scotia Hospital, Halifax, will shortly retire after thirty-five years' association with the institution, it is announced—Dr. Arthur F. Miller, superintendent of the Nova Scotia Sanatorium, Kentville, was guest of honor at a banquet, January 3, in celebration of his completion of twenty-five years of service.

LATIN AMERICA

New Director of Oswaldo Cruz Institute—Dr. Antonio Cardoso Fontes has been appointed by the Brazilian government director of the Oswaldo Cruz Institute, Rio de Janeiro, to succeed the late Dr. Carlos Chagas.

Government Services

Annual Report of the U. S. Navy

Aeronautic accidents were the leading cause of death in the U. S. Navy for 1933, displacing motor vehicle accidents, which had been in first place for the three preceding years. The major disasters included the destruction of the *Akron*, resulting in seventy-two deaths, and the crash of the *J-3* which resulted in two deaths. The lowest general admission rate ever recorded (477.03 per thousand persons in the navy) was reached in 1933. This improvement is attributed to a decreased incidence of acute catarrhal fever, influenza, for which the greatest reduction is noted, and the venereal diseases. There was no outbreak of epidemic proportions reported during the year. There were 51,606 admissions and 442 deaths from all causes in 1933. The admission rate for communicable diseases transmissible by oral and nasal discharges was 109.05 per thousand for 1933, the lowest incidence since 1923. Twenty-seven deaths were attributable to this class of diseases. Influenza caused 394 admissions and two deaths as compared with 1,637 admissions and six deaths in 1932. The admission rate for wounds and injuries in 1933 was 63.21 per thousand as compared with 60.04 for 1932. The number of injuries sustained by naval personnel when absent from their commands continues to increase 31.31 per cent of all admissions for injuries and poisonings in 1933 having been incurred while on leave or liberty. Motor vehicles were responsible for seventy-six deaths. There were 1,438 admissions and ten deaths chargeable to athletics and recreational sports during the year. There were thirty-one deaths from drowning. Venereal diseases occupied second place according to number of admissions (102.45 per thousand) and first for number of sick days (178,523). There were 7,106 admissions for acute catarrhal fever in 1933. The lowest admission rate since 1924 (468 per hundred thousand) was reached for Vincent's angina. There were 363 admissions for mumps, 141 for measles and fifty for scarlet fever. There were nine sporadic cases of diphtheria. No case of smallpox was reported. Four cases of acute anterior poliomyelitis were admitted in 1933. Twenty-one deaths from tuberculosis were reported. The disease (all forms) was responsible for 44,103 sick days. There were 392 original admissions from malaria, in twelve cases the disease was reported as existing prior to enlistment. No cases of Asiatic cholera were reported. Six original admissions were for typhoid with two deaths and three for paratyphoid with no deaths. Suicide was responsible for forty-two fatalities. There were 1,318 persons invalided from the service in 1933. A total of 1,516,658 treatment days in naval hospitals for all classes of patients was recorded, this includes 828,909 treatment days of navy personnel, 588,881 of Veterans' Administration patients, and 98,868 treatment days of all other supernumeraries. The total, however, does not include 52,828 treatment days on the hospital ship *U. S. S. Relief*, 4,280 treatment days for tuberculous patients at the naval unit, *U. S. Army Fitzsimons General Hospital*, Denver, and 9,061 treatment days for insane patients at *St. Elizabeth's Hospital*, Washington, D. C. For the year ended June 30, 1934, there were 855 commissioned medical officers in the navy, of this number 108 were on duty with the Civilian Conservation Corps in camps throughout the United States. Thirty-one medical officers were separated from the service fifteen by resignation, fifteen by retirement and one by death. Research carried on related to problems of the submarine service, deep sea diving, chemical warfare and the insecticidal fumigation of ships. There were forty-seven flight surgeons at the close of the fiscal year, thirty-four attached to aviation units.

Foreign Letters

LONDON

(From Our Regular Correspondent)

March 30, 1935

The Struggle of the Osteopaths for Registration

At the sixth sitting of the house of lords select committee on the registration of osteopaths bill, Dr. J. M. Littlejohn, who described himself as dean of the British School of Osteopathy, gave evidence. He said that he was educated at Glasgow University, where he graduated M. A. He also held the degree of D. M. of the Dunham and Hering medical colleges of Chicago and D. O. of the Kirksville School of Osteopathy. He had been professor of physiology and dean at Kirksville and professor of physiology at the National Medical School, Chicago. He established the British School of Osteopathy in 1917. The students were required to attend some school recognized by the medical profession for premedical work. He was cross-examined by Sir William Jowitt, the lawyer who appeared for the British Medical Association. Asked about his degree of LL. D., Texas, he said that this was an honorary degree conferred "for public work—in political philosophy, for example." Did he know a Mr. Looker, who had to leave America rather hurriedly and established here "the Looker College of Osteopathy and Chiropractic"? He did. Looker used to give people M. D., which meant "master diagnostician," and "F. C. B. S.," which meant "Fellow of the British Chiropractors Society." He left England and Dr. Littlejohn took over some of his students, crediting them with three years' work on the basis of test papers, which they took home to answer. Sir William Jowitt said: "I could go home and get a medical dictionary and make a good job of it." The cross-examination revealed that a student transferred from the "Looker College" received a certificate of four years' attendance at the British School of Osteopathy although he had attended only one year. This practice led to a severe attack by Sir William Jowitt on the character of Dr. Littlejohn.

THE CASE AGAINST THE BILL

A statement signed by 800 persons engaged as university professors and lecturers in research and teaching in the fields of biologic and medical science was read. Many of them are not engaged in medical practice and a number do not hold medical qualification. Among them are twenty-three fellows of the Royal Society, forty doctors of philosophy, seventy-five doctors of science and 100 masters and bachelors of science. The passage of the bill into law would not affect any of them personally. Their objections to it are based on its menace to the interests of the public and to the prestige of scientific medicine. The tenure of their posts commits them to no particular scientific theories. They state that the theory of osteopathy with its conception of "the osteopathic lesion" as the primary cause of disease is unsupported by scientific evidence. No biologist, anatomist, physiologist or pathologist of a British university has observed "the osteopathic lesion," and no evidence susceptible of verification has been brought forward. If this lesion exists, it is unbelievable that it has escaped the observation of the workers in these sciences and that evidence of scientific value can be brought forward in support of it. Biologic and medical sciences progress steadily as the result of research. Their fundamentals are based on carefully controlled observations which have stood the test of time, and it is these fundamentals that osteopathy controverts. There can be no compromise, medical science and osteopathy are contradictory. The signatories deputed five eminent teachers to give evidence on their behalf.

SIR FARQUHAR BUZZARD'S EVIDENCE

Sir Farquhar Buzzard, regius professor of medicine at Oxford said that the bill was designed to establish a system of healing the basic principle of which must be accepted by its students before they had any scientific or medical training. No medical student was asked to do this. He was put through a course of training far more thorough than that contemplated in the bill but was free to form his own opinion as to the most important single factor, if he cared to make such a generalization. From time immemorial there had been cults proclaiming a newly discovered single factor. One who had traveled in the Americas, as he has done, would be convinced that osteopathy was dying in the country of its birth. From 80 to 90 per cent of patients got well under any treatment or none, but when one of the patients of these cults got well it was invariably attributed to the treatment. Any cult at any age could produce a number of grateful patients. The testimony of the skill of osteopathic witnesses had the savor of advertisements of quack medicines. Referring to the proposal to add to the board to be set up under the bill one registered physician, Sir Farquhar Buzzard considered that this added enormously to the danger. The public would conclude not only that there was state recognition of osteopathy but also recognition by the medical profession. He criticized a book, "The Principles of Osteopathy," by Y. Castillo, professor of Kansas City College, which is widely quoted in the *British Osteopathic Review* as an authority. He had studied it with some care, especially the part on the nervous system, and was amazed at the ignorance displayed in regard to the anatomy, physiology and pathology of the spinal cord. It would be almost criminal to put it into the hands of a medical student. One figure "illustrative of the effects of the osteopathic lesion on the spinal medulla" was described as showing an area of degeneration near the tip of the posterior horn. But it was not a photograph of the posterior horn at all but of the base of the anterior horn. Of the degeneration of cells there was no evidence, the pericellular spaces were not pathologic at all and there were no swollen axis cylinders. The whole thing coming from the A. T. Still "research institute" exemplified gross ignorance of the anatomy and physiology of the spinal cord.

Thomas Malthus

The centenary of the death of Thomas Malthus was celebrated at Cambridge, where he was educated and held a fellowship at Jesus College in 1793. His famous *Essay on Population* was published anonymously in 1798. Three addresses were delivered. Dr. Bonar said that Malthus was the first to make the study of population worthy of discussion. Above all things he desired an economy of human lives by a lower death rate and lower infant mortality and a higher standard of living. The impulse that he gave to the study of these problems was even more important than his own contributions to the doctrine. Mr. Fay said that Malthus's distinctive contribution lay in the field of social economy. Presuming to dispense misery and vice with the certainty of a Benthamite in holy orders he raised angry protests. On the other hand his doctrine was germinal to the researches of Darwin and the theory of evolution. Mr. Keynes showed how to the poets Shelley and Coleridge Malthus appeared as a symbol of the sophisms of the economists, who could prove by means of truisms that all attempts to mitigate poverty and misery were destined to increase it. Such a charge directed against the economists of the nineteenth century was not wholly false.

Malaria in Ceylon

The latest official statistics of malaria in Ceylon show that more than 38,000 persons have died of malaria and allied causes during the three months of the epidemic. Comparison of the

mortality from all causes shows that the deaths in the period November 1934 to January 1935 totaled 68,193, while those in the corresponding period of a year ago were only 30,037. The council has voted \$366,500 for the relief of malaria victims.

An Anthropometric Survey of Great Britain

Britain has lagged behind many other countries in organized research into the racial history and present physical constitution of its people, though individual efforts of some magnitude, particularly the work of Beddoe on "The Races of Britain," have covered parts of the country. The Royal Anthropological Society wishes to set on foot a comprehensive survey of the past and present population of Great Britain. This will involve the arduous collection, reduction, mapping and interpretation from more than one point of view of a mass of data by a number of trained workers who can be found if the funds are available. Money will be required (1) to give grants to workers who would take exact measurements of groups of living people and of skeletal remains preserved in museums or elsewhere, (2) to pay for the necessary instruments, (3) to pay the traveling expenses of the workers, and (4) to help in the publishing of scientific reports and popular summaries of the results obtained. The society holds that such a survey would lead to conclusions of both scientific and national importance, which would throw light not only on our history but also on sociological and medical questions. It therefore asks for donations in aid of the projected anthropometric survey of Great Britain, to be sent to the Hon. Treasurer, Royal Anthropological Institute, 52 Upper Bedford Place, London, W. C. 1.

The Noise of Motorcycles

The authorities of Paris have finally decided to control the noise made by the exhausts on motorcycles. Any one who has attempted to sleep while motorcyclists were allowed to make night hideous, while proceeding at full speed with open exhausts on residence streets, will welcome this attempt to control a noise nuisance far worse than that of the automobile siren, already suppressed in Paris at 11 p. m.

The police department is testing all kinds of devices, in spite of protests on the part of motorcyclists that such suppression will interfere with the utility of the machine. The same sort of opposition was encountered a number of years ago, when automobilists maintained that suppression of the escape of smoke from the exhaust pipes would prevent the further use of automobiles.

Information Bureau for Foreign Physicians

In 1920 an office was opened in the buildings of the Paris Faculté de médecine in order to aid visiting physicians and students regarding courses of study in the school. Since then the bureau has been directed by Prof. Henri Hartmann, aided by Miss Alice Huré, both of whom speak English. The annual report submitted by the director, February 23, contains some interesting information. Before the crisis the number of foreign physicians and students who applied for information rose as high as 1,200 per annum. During the last four years this figure has been as low as 1,080. The world crisis, however, is not the only cause of the diminution. A few years ago many students from the United States and Canada matriculated in French medical schools receiving a so-called honorary degree, which did not entitle them to practice in France but permitted them to do so in the United States and Canada, after simply passing a state board examination. Since not only the state boards of these countries but also those of some European

countries no longer accept such honorary degrees as the equivalent of graduation from their own school, few students of this category now come to France. As a result of the recent riots against foreign medical students, the number of the latter will be greatly diminished. In the provincial hospitals there is no competitive examination for internships and many such positions have been filled by foreigners, to the detriment of French students. The authorities in the country districts have also permitted foreign students to act as temporary substitutes for practitioners, which is a violation of the law. The number of state diplomas that entitle the holder to practice medicine has increased from forty-nine in 1930 to ninety-seven in 1934. Rumanian students have taken advantage of an old treaty that dispensed with the bachelor of arts degree otherwise required for matriculation in the medical schools. This advantage is practically a dead letter at present, since the enforcement of the Armbruster law referred to in previous letters.

Professor Hartmann is of the opinion that all foreign students who do not propose to remain in France should be welcomed as in the past, in order that they may carry home with them the French methods of teaching medicine and other sciences. The small number of foreigners who have been given internships should not give the native students any cause to maintain that French interns are being crowded out by foreigners. In 1930 the latter constituted only 7.6 per cent of the interns in the Paris hospitals and in 1934 only 4.7 per cent.

Opposition to Foreign Physicians

At a meeting of a committee representing all the medical societies of Paris, February 12, the following resolutions were passed:

1 Foreigners who wish to obtain a state license to practice in France or its colonies must comply with the usual requirements as to preliminary education (French bachelor of arts degree) before being admitted to a medical school.

2 No foreigner shall be permitted to change his honorary diploma, called "diplome universitaire," which does not carry with it the privilege to practice, into a state diploma, which does bestow such a right to practice.

3 No foreigner above the age of 30 will be allowed to become a French citizen unless he shall, before such age, have been in the military service for the length of time required of every native-born French citizen.

4 No foreigner shall be permitted to practice medicine unless he or she has been naturalized at least ten years before beginning to practice.

5 All public hospitals are requested to discharge alien physicians and students now in their employ and to replace them by French citizens. Any foreigner now practicing without a French state license shall be prosecuted.

Social Insurance for Illness

French social insurance permits payment of benefits for the same illness during a period not longer than six months. The Concours medical discusses this rather arbitrary feature of the law and asks how frequently a physician is called on to treat an ailment such as syphilis, tuberculosis and cancer, the duration of which extends far beyond the period of six months during which payments are allowed. It seems unjust to refuse further financial aid to such individuals. There has been some relief in the fact that the same paragraph of the law states that every relapse occurring during any two months of the disease is considered as a continuation of the original illness, so that the benefits in the form of payments ought not to cease. Another portion of the law stated that every relapse which took place more than two months after apparent cure of the original ailment must be considered as a new ailment and entitled again to a new payment period of six months.

The result of these conflicting paragraphs of the law was that the assured automatically had the right to receive payment for illness during any number of six months periods interrupted by two months periods when nothing was paid. According to a recent decision by the courts, the two months period during which nothing was paid has been suppressed, thus assuring continuous benefits for chronic ailments of more than six months' duration.

These conflicts show the necessity of constant changes in any social insurance law.

Can Exposure to the Sun Produce Cancer?

So much publicity followed the report of experiments on mice by Professor Roffo of Buenos Aires that a committee composed of Roussi, Hartmann and Beclere was appointed by the Academy of Medicine of Paris to verify those observations. The original paper appeared in the December 1934 bulletin of the Association for the Study of Cancer, and the report of the committee was made Dec. 26, 1934. Two previous communications have been published, one by Findlay and the other by Putscher and Holtz, both in 1930. In the former, twenty mice were exposed to the action of ultraviolet rays over areas where the hair had been removed by sodium sulphide. Typical epitheliomas were found. In the experiments of Putscher and Holtz the results were the same, after exposure of the ears without depilation.

Roffo employed the entire solar rays and was successful with mice in obtaining typical carcinomas and a fusocellular type of sarcoma after from seven to ten months of exposure. Two types of lesions have been noted: first, an epithelioma of the ear, which begins as a hyperkeratosis and develops into a typical cancer at the end of from seven to eight months; second, a sarcoma, which may develop without preceding keratosis. The animals usually die between the tenth and twelfth months of cachexia and metastases in the cervical lymph nodes. As a rule the tumors develop in areas where there are no hairs, such as the ears in 140, the eyes in fifty-eight and the paws in fifteen cases. Histologically the eye tumors have the appearance of spindle cell sarcoma, while those of the ears, that of either an epithelioma or sarcoma. The committee of the Academy of Medicine was able to verify the observations of Professor Roffo in slides submitted by him for examination. In some experiments the tumor presented the structure of both an epithelioma and a spindle cell sarcoma. Roffo believes that some biochemical change in the form of a local hypercholesteremia takes place as the result of the exposure to the ultraviolet rays of the sun. The result is the transformation of the normal into a neoplastic cell. Although rats and mice are especially sensitive to ultraviolet rays, the committee concluded by directing the attention of individuals who abuse sun baths to the potential danger of such exposures.

Americans Decorated

Two members of the American medical colony of Paris were recently honored by the French government. In recognition of their services in the fields of research and of general surgery respectively, Drs. Harry Plotz of the Pasteur Institute and Charles Bove of the American Hospital were made chevaliers of the Legion of Honor, an order founded by Napoleon I as a national recognition of important achievements by both men and women in the sciences, literature, art and music. Dr. Plotz is doing some remarkable work at the Pasteur Institute on the etiology of various infectious diseases. Dr. Bove is associate surgeon at the American Hospital here.

Dr. Zinsser in Paris

Dr. Hans Zinsser of Boston, exchange professor from Harvard to the University of Paris, is engaged in continuing his typhus studies at the Pasteur Institute. He is working in a

laboratory placed at his disposal by Professor Nicolle and is also giving lectures assigned to him by Professor Debre in the courses in bacteriology at the Faculté de médecine

Professor Guérin Elected Fellow of the Academy

In recognition of his distinguished service, Professor Guérin of the Pasteur Institute has just been elected a fellow of the Academy of Medicine of France one of the highest honors that can be bestowed on a member of the profession. Professor Guérin is at present director of the antituberculosis vaccination service of the Pasteur Institute of Paris. In association with the late Professor Calmette, he discovered the vaccine known as the BCG vaccine.

Vaccinal Encephalitis

The end of 1934, the sixtieth anniversary of the federal vaccination law to combat smallpox was celebrated in Germany. In this connection Professor Catel, pediatrician, of Leipzig, gave a detailed discussion of vaccinal encephalitis. The increasing number of cases of encephalitis occurring in recent years following vaccination against smallpox caused anxiety among the public and raised the question of changes in the vaccination law for the prevention of smallpox. (THE JOURNAL, June 23, 1934, p 2126) Sporadic cases of vaccinal encephalitis were reported a number of years ago, but an increased incidence was announced first in England in 1922, in the Netherlands in 1923, and in Germany, Austria and Czechoslovakia since 1924. From the epidemiologic point of view the manifestations of encephalitis are not fully understood. For example, in one district of England there were several cases, while in another district, in spite of the fact that the percentage of vaccinations was equally high, there was not a single case. In the Netherlands the incidence is highest in the smaller rural communes, while in Germany there are more cases in the larger cities. No connection between vaccinal encephalitis, on the one hand, and the quality of the lymph employed or the potency of the local vaccinal reaction has been demonstrated with certainty. The technic used in the application of the vaccine has no significance (THE JOURNAL, February 23, p 666). Encephalitis occurs also following intracutaneous vaccination. Persons vaccinated for the first time develop encephalitis much more frequently than revaccinated persons. There appears to be a connection between the frequency of vaccinal encephalitis on the one hand, and the extent to which vaccination is applied (maximum in May and June) and the increased incidence of other, para-infectious encephalitides (but not Economo's epidemic encephalitis). Neither sex is more affected than the other, nor is any particular age group especially predisposed. The observation that in Germany children between the ages of 1 and 2 are most affected is explained by the fact that most children receive their first vaccination during that period. The mortality is high in England from 58 to 65 per cent in Germany 34 per cent, and in the Netherlands 30.9 per cent. The incubation period ranges from two to thirty-four days, with an average of from eleven to fourteen days. From the anatomopathologic point of view the white substance of the brain is more frequently involved, but the gray substance may be affected. In contrast with epidemic encephalitis (in which foci are found only in the midbrain and the substantia nigra), in vaccinal encephalitis there are disseminated foci in the brain and in the spinal cord (meningo-encephalomyelitis). Taken histologically, there are perivascular, small-cell (lymphocytic) infiltrations, glia proliferations and degeneration of medullary

sheath and axis cylinder. The most obscure feature is the etiology. On the basis of the available researches, which have extended to the demonstration of the presence of the vaccine virus in the brain of persons who have died of vaccinal encephalitis, and also to investigations on experimental animals, the possibility of direct connections between the artificial infection brought about by the vaccine lymph and the appearance of the encephalitis cannot be denied. There is, however, another possibility to be considered, namely, a lowering of the immunity of the organism as a result of the vaccination, whereby previously latent and harmless agents acquire pathogenic importance. Recurrences have been observed even after twelve months. This is important for the differential diagnosis as against poliomyelitis, which almost without exception presents no recurrence. The original assumption that vaccinal encephalitis ends either in death or in complete recovery has been found to be erroneous. Permanent injuries have been found: mental disturbances, hemiplegia spastica infantilis, paresis, contractures and disturbances of the gait. With regard to the therapy, the observations on the effects of injections of serum of vaccinated children are not extensive as yet. Possibly a trial of mother's blood should be made. What conclusions may be drawn from the appearance of vaccinal encephalitis? In Germany, 1,500,000 persons are vaccinated annually for the first time, and about the same number are revaccinated. The largest number of disorders of the central nervous system were reported in 1928 (twenty-eight cases), whereas in that year in England, where vaccination is not compulsory but is a matter of conscience, 12,400 persons developed smallpox, as against two persons in Germany. Hence the cases of vaccinal encephalitis though regrettable, do not justify any weakening of the law providing for compulsory vaccination.

Hereditary and Environmental Influences in Twin Births

Professor Lenz, occupant of the chair of eugenics addressed the Berlin Medical Society on the subject of "Hereditary Influence and Environmental Influence in Twin Births." Research on twins is regarded as an important field of investigation and is being carried on in a number of institutes in Germany (THE JOURNAL, Nov 1, 1934, p 1721). Whereas in dizygotic twins both hereditary and environmental influences are observable, enzygotic twins, being the expression of the same hereditary mass, are to be regarded as subject only to environmental influences. Differences due to hereditary and environmental influences are not to be conceived of in the manner that Lenz himself formerly considered possible, namely, that they need be only added together in making serial comparisons. He has found, on further investigation, that a different formula must be set up after this type. The average differentiation increases with the square root of the hereditary units involved. This principle applies equally to the hereditary mass and to the environmental influences. Further computations dealing with the determination of the minimum of hereditary influence have brought out the following important fact. The hereditary influences predominate considerably over the environmental influences, they are not equal, as was formerly believed.

In all methods of hereditary research it must be considered that nearly all determinations are affected by a strong element of error. For example, momentary fluctuations in comparative blood sugar determinations, on which many conclusions are now based, have not always been taken into account, or unlike measuring factors such as intelligence and character have been compared. Such instances have been frequent in hereditary research in the past and have been great sources of error.

It must not be forgotten that it would be an error to expect to obtain any exact figures on the relation of environmental and hereditary factors. The figures secured must be considered only as relatively true. Recognition of this fact does not, however, make out hereditary research to be worthless, as Lenz emphasized. One thing, to be sure, can already be foreseen: all future experiments, which will always be laborious, will show, on the average, less difference in physiologic researches on enzygotic than on dizygotic twins. Through hereditary research no further fundamental principles will be discovered, the limitations of hereditary research on twins have already been reached. It has shown that the basis of all human aptitudes and talents is hereditary. The results of general hereditary research would not, however, always be identical, since they will depend on the nature of the population from which they are derived. The purer the antecedents of a race are, the greater importance will attach to the environment. Important for future investigations are clearness, exact definition of the term *erblichkeit*, or hereditability, and fruitful collaboration between the clinical specialist and the biologist trained in matters of heredity. Only through such collaboration can a useful pathology of heredity be produced.

The Spread of Trachoma in Germany

In taking the census of infirm persons in Germany in 1926, it was found that 105 per cent of this group had become blind as a result of trachoma. According to the statistics of the period 1924-1930, an average of 1,949 cases of trachoma annually were notified. The incidence of the disease is greater in some sections than in others. Investigation has revealed that intrafamilial infection plays a predominant part in the transmission of trachoma, as against the possibility of infection outside the family. The cases of trachoma occurring among the population of the German reich may be divided into three groups: (1) cases that are brought in from so-called trachoma regions, mostly by migratory laborers from the countries along the eastern frontier, or from East Prussia and Silesia (the two Prussian provinces in which trachoma is highly prevalent), (2) sporadic cases occurring in regions commonly free from the disease, and (3) cases occurring in certain regions of Germany, which are known to be endemic foci. The countries chiefly involved in the dissemination of trachoma across the border are Poland and Russia. Since at least half of the cases of trachoma occurring in the regions of Germany in which trachoma is little known have been brought in from outside, a more strict examination of immigrants by ophthalmologists is needed, which should include not only foreigners but also nationals from regions in which trachoma is widely prevalent. In addition, greater attention should be given to intrafamilial infection.

Aniline Poisoning Due to Shoe Dyes

It is a matter of common knowledge that even small quantities of aniline or nitrobenzene lead to the formation of methemoglobin and may prove fatal. But it is not yet sufficiently known that these substances are used in the manufacture of shoe dyes. Some time ago the federal bureau of health called attention to the disturbances of health traceable to these substances and prohibited their use as well as that of orthotoluidine. Recently it became known that, in spite of such prohibition, some firms are again adding aniline or orthotoluidine in considerable quantities to their shoe dyes. Investigations by the bureau of health and by other scientific bodies revealed that no definite percentage of these substances can be assigned that on the one hand, excludes injuries to health, and on the other hand, meets the technical requirements. Hence the demand has been renewed that these substances be not used for anything worn on the body. In this connection

it may be mentioned that in infants cyanosis has been observed that was caused by the ink used to mark undergarments. Regulations governing such matters will soon be issued.

The German Roentgen Society

Until recently, Germany had a considerable number of roentgenologic societies, some of which had scientific and some economic aims. It has now been ordered that the "Deutsche Röntgen-Gesellschaft" shall be the only roentgenologic society in Germany. All other societies in this field have been dissolved.

Danzig's New Academy of Practical Medicine

The senate of the Free State Danzig has decided to establish a "Staatliche Akademie für praktische Medizin," which will offer educational facilities for older students and for continuation courses for physicians. The methods of instruction will be distinctly different from those in use in Germany, for example, the clinical lectures will be regarded as of less importance than the drill and laboratory courses. The clinical instruction will accordingly be given chiefly at the bedside instead of in the auditorium. Hence the propedeutic clinical lectures will be omitted from the curriculum. The University of Danzig is accredited in Germany, and graduates are admitted to the 'state examination' held in the reich.

JAPAN

(From Our Regular Correspondent)

Feb 25, 1935

Campaign Against Leprosy

The number of lepers in Japan, which was 15,000 in 1930, has since then been on the increase. Gravely concerned over the situation, the home office has found it necessary to carry out its plans on a large scale. The budget for the next year that has passed the lower house includes 480,000 yen for the operation of the existing state leprosariums, 360,000 yen to subsidize the private hospitals and 30,000 yen to cover general expenses incidental to the antileprosy campaign. A census will be taken on March 31 of the lepers throughout the country in order that a definite plan may be mapped out within the bounds of the budget.

Student Association for the Prevention of Tuberculosis

The increase of tuberculosis among the students of all kinds of schools has so strongly impressed the medical students in the Tokyo and the Kyoto imperial universities that they have decided to establish an association for the purpose of combating tuberculosis in students. They are going to work with their professors as advisers, but the work and administration are to be done by themselves. The first task will be the thorough physical examination of all the students in their own university and then the opening of the consultation office and the building of sanatoriums. With aid and encouragement by the members of the faculty, this work is expected to get under way before long, to the great pleasure of all of the students.

Opium in Chosen

It was officially revealed, February 16, that a new law imposing far heavier punishment on persons engaged in the illicit traffic in opium than is provided for in the present law will be enforced throughout Chosen, May 1. The Chosen government and the home and the overseas affairs offices of Japan proper have approved the measure in order to check the growing number of opium addicts in the peninsula. The number of opium eaters there is roughly estimated to be 10,000. It is next to impossible to prevent illicit traffic in this dangerous drug under the present law, which provides maximum prison terms of three months or fines under 100 yen for its violation. The new law as enforced in Japan proper at present, will provide

the maximum jail terms up to five years and fines up to 5 000 yen. The new law will conform with the spirit of the international opium convention of 1931, to which, of course, Japan is a party.

Division of Medical Service

For many years there has been a controversy between physicians and pharmacists on the division of medical service, that is that physicians shall prescribe medicine and pharmacists prepare and sell it. For the last few years it has seemed that pharmacists have been at a disadvantage in the matter, but late this month it was revealed that a bill might be presented to the diet on the division of medicine. With a view to checking the passing of the bill, a mass meeting was held in Tokyo, 4 000 medical practitioners attending from all over the land, and their movement to oppose the bill was successful. The Japan Pharmacist Association also held a meeting. The diet was in favor of passing the bill but through the efforts of the Japanese Medical Association the situation has undergone so much change that the bill has almost no hope now. Medical men have great political influence. Physicians are generally men of importance in the country and the legislators can hardly oppose their power and influence. The medical association has issued a statement showing that if this bill passes it will be to the great inconvenience of patients in that they must then pay both a medical fee to the doctor and a preparation fee and the cost of medicine to the pharmacist, and of course they must then go to the trouble of visiting the two offices. The relation between physicians and patients will become mercantile and less humane. From the social standpoint a tendency would develop to go to the pharmacist without consulting the doctor. Early discovery of an infectious disease would be delayed. The prescriptions made known to others than the patients would disclose secrets that have heretofore been kept by the doctor. At present patients have free choice of physicians and pharmacists. The number of pharmacists is almost 30 000 with 2 000 graduates every year from various schools of pharmacy. The controversy will go on.

BUDAPEST

(From Our Regular Correspondent)

March 23 1935

The Campaign Against Cancer

When Prof Ferdinand Blumenthal founder of the Berlin Cancer Research Institute, had to leave his position in 1933 at the time of the transformation in Germany he was invited by the faculty of medicine of Belgrade University to establish the Yugoslavian cancer research institute. Professor Blumenthal accepted the invitation and while en route to Belgrade to occupy this position stopped some days in Budapest to lecture about the present campaign against cancer. He said that when he was the assistant of Professor Leyden in Berlin from 1913 on he established the fact that a successful campaign against cancer necessitates having a special institute. He prepared plans, which the authorities accepted and in 1917 the institute began its activity. The pathologist Orth was in charge of research and Blumenthal headed the clinical service. After Professor Orth's death he became the only head of the institute which then consisted of two wards and one laboratory. When he surrendered it two years ago it was an institute of vast extension with a separate radiologic section with a polyclinic and an experimental section. The polyclinic recorded more than 100 patients a day. There was only one similar institute in Germany, and that was at Heidelberg University.

Professor Blumenthal said. When my institute in Berlin was started it was the first place where systematic x-ray and radium treatment was given. Up to then medical science had only one weapon against cancer and that was the operating

knife. We had to make a great fight for the recognition of radiotherapy. Today ray treatment is not only a competitor to surgery but in inoperable cancers of the tongue and intestine it is a proved, competent method. The ray treatment has its limitations, because it is only the local treatment of cancer, and in those cases in which cancer is already general in the organism, ray treatment is of no avail.

'In recent years various scientific institutes have initiated extensive researches to find methods outside the territory of surgical and ray treatment to conquer cancer. They have succeeded in finding serums and chemical compounds which in certain instances have proved efficacious against cancer. Another great achievement was that they succeeded in establishing the effect of dietetic regimens on cancer. It is chiefly the vitamins which as a means for promoting growth administered in the cancer diet, seem to offer encouraging ground for experiments. When blood tests are further developed, it will be possible to establish early exact diagnoses in doubtful cases and then cancer will lose its importance as an incurable disease. Even at present it is possible to cure a cancer patient who presents himself at an early date before the generalization of the process and entrusts himself to the hands of a competent physician instead of running himself by the concoctions of quacks.'

A New Journal of Cancer

Acta cancerologica is the title of a new publication dealing with all aspects of cancer. It is published in Budapest and is edited by Dr Gereb, assisted by Professor Blumenthal, now director of the cancer institute in Belgrade. Papers will be published in German, French and English. The first issue, which appeared recently contained ten communications. If the editors can maintain the high level of the first number, the journal should be successful.

The Tenth Tuberculosis Dispensary in Budapest

The city of Budapest is endeavoring to build tuberculosis dispensaries at the rate of at least one to each 100,000 of population. The tenth dispensary has just been opened, its building and equipment costing 300 000 pengos (about \$90,000). The ten dispensaries are under the control of Dr Joseph Parassin, lecturer to the University of Budapest, and a staff of twenty-nine physicians forty nurses and twenty-two health officers. The maintenance of the ten dispensaries costs 562,000 pengos (\$154 000) annually. The number of consultations rendered last year was 236 000 and the number of new patients was 17 674.

Deaths

Fielding Hudson Garrison ♂ Colonel, U S Army, retired, Baltimore, most eminent American medical historian, died, April 18, at the Johns Hopkins Hospital, aged 64. Dr Garrison was born in Washington, D C, Nov 5, 1870. He received the bachelor of arts degree at Johns Hopkins University in 1890, and his medical degree from Georgetown University School of Medicine, Washington, D C, in 1893. During a thirty-three year period from 1889 to 1922 he was assistant librarian at the Army Medical Library in Washington. At the entrance of the United States in the World War in 1917 he was ordered to active duty as a major in the medical reserve corps and later was promoted to the rank of lieutenant colonel. He was commissioned lieutenant colonel in the regular army in 1920 and in 1930 was retired as a colonel for disability in line of duty. During the war Colonel Garrison remained on duty at the Surgeon General's Library and also served in various training camps in the South and West during which service he assisted in compiling data for the history of the medical department in the World War. He served in the Philippines from 1922 to 1924, and in 1925 he was appointed consulting librarian to the New York Academy of Medicine. In 1930 he was appointed librarian of the Welch Medical Library at Johns Hopkins University School of Medicine and also resident lecturer in the history of medicine.

Colonel Garrison was the co-editor of the *Index Medicus* at the Surgeon General's Library from 1903 to 1912 and editor of the *Index Medicus* from 1912 to 1927, when that famous publication became affiliated with the *Quarterly Cumulative Index* which had been published by the American Medical Association for some years. He was an Affiliate Fellow of the American Medical Association, a past president of the American Association for the History of Medicine, member of the Medical Society of the District of Columbia, fellow of the American College of Surgeons, and a member of the history section of the Royal Society of Medicine of London and of medical societies in Germany and France. His book "An Outline of Medical History" is recognized as a classic throughout the civilized world. He was the author also of numerous monographs and was frequently invited to deliver lectures before special groups on medical history a subject to which his life was fully and masterfully devoted.

Colonel Garrison was a prodigious worker, frequently spending eighteen hours daily in developing the early issues of the *Index Medicus*. His memory was amazing. His friends knew him as a scholar, a lover of music and all of the arts, a genial companion, a gracious friend.

John Smyth, New Orleans, Tulane University of Louisiana Medical Department New Orleans, 1900 member of the Louisiana State Medical Society, the Southern Surgical Association and the American Association for Thoracic Surgery, fellow of the American College of Surgeons, formerly professor of clinical surgery at his alma mater, member of the surgical staffs of the Hotel Dieu and Southern Baptist hospitals and consulting surgeon to the Charity Hospital, aged 65 died, February 25.

Eugene L'Hommedieu Swift ♂ Major, U S Army, retired Berkeley, Calif., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1884, entered the Army as assistant surgeon in 1887 and was promoted through the various grades to that of major in 1901 in which year he retired, veteran of the Spanish-American War returned to active duty during the World War aged 71 died, March 16 of carcinomatosis.

Edmond John Labbe ♂ Portland, Ore., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895 emeritus professor of obstetrics University of Oregon Medical School, served during the World War member of the North Pacific Surgical Association, on the staff of the Doernbecher Memorial Hospital for Children, aged 62, died, February 20, of cerebral hemorrhage.

Herman Frederick William Flock ♂ Williamsport, Pa., Jefferson Medical College of Philadelphia, 1920 member of the American Academy of Ophthalmology and Oto-Laryngology, fellow of the American College of Surgeons on the staff of the Williamsport Hospital aged 39 died, March 6, in the Temple University Hospital Philadelphia of streptococcal cellulitis.

Adolph Monaelesser ♂ New York, Eclectic Medical College of the City of New York 1882 University of the City of New York Medical Department 1886 member of the American Urological Association veteran of the Spanish-American War for many years on the staff of St Elizabeth's Hospital aged 79 died March 27 of chronic leukemia.

William Watson Laing, Brooklyn, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1894, member of the Medical Society of the State of New York, served during the World War, on the staffs of the Brooklyn State Hospital and the Wyckoff Heights Hospital, aged 63, died, April 4, of pneumonia.

Walter Bright Rile, Sunmount, N Y Hahnemann Medical College and Hospital of Philadelphia, 1902, Jefferson Medical College of Philadelphia, 1921, fellow of the American College of Surgeons, served during the World War, aged 59, on the staff of the Veterans Administration Facility, where he died, February 27, of cerebral hemorrhage.

William Wickham Mills, Chappaqua, N Y, Bellevue Hospital Medical College, New York, 1897, member of the Medical Society of the State of New York, formerly county coroner and deputy health commissioner aged 64, on the staff of the Northern Westchester Hospital, Mount Kisco, where he died, March 31, of peritonitis.

Roland Gordon Holt ♂ Schenectady, N Y, Columbia University College of Physicians and Surgeons, New York, 1907, formerly instructor in obstetrics Albany Medical College served during the World War, aged 53, on the staff of the Ellis Hospital, where he died, March 29, of acute cholangitis.

John Mitchell Rogers, Barnesville, Ga., Atlanta College of Physicians and Surgeons, 1900, member of the Medical Association of Georgia secretary and past president of the Lamar County Medical Society formerly chairman of the county board of health aged 59, died February 28, of bronchopneumonia.

William Sessions Hannah ♂ Montgomery, Ala., Johns Hopkins University School of Medicine Baltimore, 1924, past president of the Montgomery County Medical Society, aged 34, died, March 22, in the Buffalo (N Y) General Hospital, of streptococcal septicemia.

George Washington Martin, Portsmouth, Ohio Eclectic Medical Institute, Cincinnati, 1908, member of the Ohio State Medical Association aged 51 on the staff of the Portsmouth General Hospital, where he died, April 2, of bronchopneumonia and cerebral hemorrhage.

Lewis Henry Lamkin, Natchez, Miss., University of Louisiana Medical Department, New Orleans, 1881, member of the Mississippi State Medical Association, past president of the Homochitto Valley Medical Society, aged 75, died, February 19, in New Orleans.

Allen Mason Thomas, New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1880, member of the Medical Society of the State of New York, aged 79, died, March 18, of chronic pulmonary emphysema.

William Henser Acton, Alabama City, Ala., Vanderbilt University School of Medicine, Nashville, Tenn., 1888, member of the Medical Association of the State of Alabama aged 73, died, March 18, in Gadsden, of bilateral hydronephrosis and prostatitis.

James Hunt Royster ♂ Richmond, Va., Jefferson Medical College of Philadelphia, 1917, served during the World War, fellow of the American College of Physicians, on the staff of the Westbrook Sanatorium, aged 42, died, March 22, of heart disease.

Alan Fleming McLaughlin, Richmond, Ill., University of Illinois College of Medicine, Chicago, 1930, member of the Illinois State Medical Society, aged 29, on the staff of the Sherman Hospital, Elgin, where he died, March 17, of pneumonia.

James Robert Bone ♂ Lebanon, Tenn., University of Nashville Medical Department, 1908, secretary of the Wilson County Medical Society formerly on the staff of the Martha Gaston Hospital aged 57, died March 28, of lobar pneumonia.

Thomas Breckenridge Semans ♂ Uniontown, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1920, fellow of the American College of Surgeons, on the staff of the Uniontown Hospital, aged 40, died, February 26.

Frank Hayward Collins, Goldendale, Wash., St Louis University School of Medicine, 1903, member of the Washington State Medical Association, served during the World War, aged 63, died, March 18, of coronary thrombosis.

Frederick Rudolph Larson, Omaha Northwestern University Medical School, Chicago, 1930 member of the Illinois State Medical Society, aged 43, died January 1, in the Veterans' Administration Facility, New York.

Clyde Alexander Finley, Galesburg, Ill., University and Bellevue Hospital Medical College, New York 1903 aged 57, on the staff of St Mary's Hospital, where he died, March 12, of chronic myocarditis and chronic nephritis.

Willie Hamilton O'Banion, Lockhart, Texas, Vanderbilt University School of Medicine, Nashville, Tenn, 1894, member of the State Medical Association of Texas, aged 65, died, February 11, of cardiovascular renal disease

Gilbert A Kelley ♂ Bridgeport, Calif., College of Physicians and Surgeons, medical department of the University of Southern California, Los Angeles, 1913, aged 45, died, January 27, in Reno, Nev., of cerebral hemorrhage

Jacob Franklin Meyers, Elliott, Iowa, State University of Iowa College of Medicine, Iowa City, 1903, past president of the Montgomery County Medical Society, aged 56, died, February 23, of carcinoma of the colon

James Sime Wardlaw, Galt, Ont., Canada, Trinity Medical College Toronto 1888, Queen's University Faculty of Medicine, Kingston, 1888, University of Toronto Faculty of Medicine, 1890, aged 83, died, February 22

Albert A J Lang, Jamestown, N D., McGill University Faculty of Medicine, Montreal Que., Canada 1898, member of the North Dakota State Medical Association, aged 69, died suddenly, March 18, of heart disease

Courtland F Quinby, West Grove Pa., Hahnemann Medical College of Philadelphia 1877, aged 78, died, January 11, in the Homeopathic Hospital, Wilmington, Del., of chronic nephritis and tonsillitis

Ira Price Burdine ♂ Amory, Miss., Tulane University of Louisiana Medical Department New Orleans 1892, on the staff of the Gilmore Sanitarium, aged 69, died, February 13, of chronic nephritis and uremia

Arthur Johnson, Clanton, Ala., Vanderbilt University School of Medicine, Nashville, Tenn., 1909, member of the Medical Association of the State of Alabama, aged 47, died, March 21, of lobar pneumonia

George Harry Ferguson, Saginaw, Mich., Saginaw Valley Medical College, 1901, member of the Michigan State Medical Society, on the staff of St Luke's Hospital, aged 57, died, March 1, of heart disease.

John Wesley Tildon Sr., East Orange, N J., Illinois Medical College, Chicago, 1907, member of the Medical Society of New Jersey, aged 72, died, February 1, of pulmonary embolism and arteriosclerosis

John Hiram Beane, Burlington, Vt., University of Vermont College of Medicine Burlington, 1896, member of the Vermont State Medical Society, aged 66, died, March 25, of gangrenous appendicitis

James M Mershimer, Chicago, Baltimore University School of Medicine, 1899, aged 73, died, April 8, of chronic cholecystitis, following an operation for relief of obstruction of the common duct

Jacob Lewengood, New York, Bellevue Hospital Medical College New York, 1882, for many years attending physician to the Hebrew Orphan Asylum, aged 73, died, March 26, of cerebral thrombosis

Charles F W Eberlein, Gauting, Germany, Rush Medical College, Chicago, 1879, formerly senior physician at the Chicago State Hospital, Dunning, Ill., aged 80, died, February 25, of chronic myocarditis

Cornelius Van Dyck Basten, Kearney, Neb., State University of Iowa College of Homeopathic Medicine, Iowa City 1883, aged 75, died, February 28, of carcinoma of the stomach with metastasis

Robert Means Lawrence, Boston, Harvard University Medical School, Boston, 1873, member of the Massachusetts Medical Society, aged 87, died, March 7, of myocarditis and hypertension

Henry J Swedlaw, Birmingham Ala., Birmingham Medical College, 1907, member of the Medical Association of the State of Alabama, aged 52, died, March 20, of coronary thrombosis

John H Martin, Greenville Pa., Chicago Homeopathic Medical College, 1885, member of the Medical Society of the State of Pennsylvania, aged 78, died, March 2, of lobar pneumonia

John James McNulty, New York, College of Physicians and Surgeons Medical Department of Columbia College New York, 1877, aged 78, died, February 11, of chronic myocarditis

William Alexander McRobert, Joliet Ill., Chicago Homeopathic Medical College, 1902, served during the World War, aged 67, died, January 20, of myocarditis and nephritis

James I Richard, New Orleans, Tulane University of Louisiana Medical Department, New Orleans 1892, aged 65, died, March 17, in the Toussaint Infirmary, of cerebral hemorrhage

John Fisher, Chicago, College of Physicians and Surgeons of Chicago 1887, member of the Illinois State Medical Society, aged 84, died, March 27, of cerebromalacia and arteriosclerosis

Asa Wolverton Mair, Detroit, McGill University Faculty of Medicine, Montreal, Que., Canada, 1892, aged 73, died, March 13, of mesenteric thrombosis and chronic myocarditis

John Edd Furry, Springfield, Ohio, Medical College of Ohio, Cincinnati, 1899, formerly mayor of Springfield, aged 65, died, March 13, of diabetes mellitus and arteriosclerosis

Frank Waring Lewis, Richmond, Va., Medical College of Virginia, Richmond, 1913, member of the Medical Society of Virginia, aged 46, died, March 2, of pancreatic necrosis

William Hubert Austin, Griffin, Ga., Atlanta School of Medicine, 1910, member of the Medical Association of Georgia, aged 59, died, March 15, of carcinoma of the prostate.

John C Schutzbach ♂ Strasburg, Ohio, Columbus Medical College, 1891, for many years member of the board of education, aged 65, died, March 14, of coronary thrombosis

Anthony Joseph Roderick, New Bedford, Mass., Tufts College Medical School, Boston, 1915, served during the World War, aged 43, died, February 21, of lymphatic leukemia

James Albert Dickson, Hamilton, Ont., Canada, McGill University Faculty of Medicine, Montreal, Que., 1887, L R C P., F R C S., Edinburgh, 1887, aged 75, died, March 21

Samuel Zussman, San Francisco, Universite de Strasbourg faculte de medecine 1888, member of the California Medical Association, aged 70, was found dead, February 3

John Joseph Hanavan, East Aurora, N Y., University of Buffalo School of Medicine 1906, served during the World War, aged 50, died, March 25, of heart disease

Hubbard C Raynor, Grand Rapids, Mich., Michigan College of Medicine and Surgery, Detroit, 1897, aged 64, died, March 25, in a local hospital, of gastric ulcer

Louis William Perman, Brooklyn, University of Illinois College of Medicine, Chicago, 1925, aged 39, died, February 24, in the Jewish Hospital, of lobar pneumonia

Stuart Wakeman Sherwood, Norwalk, Conn., University of Pennsylvania Department of Medicine, Philadelphia, 1902, aged 61, died, March 13, of heart disease

Alfred S Lockhart, Toronto, Ont., Canada, Queen's University Faculty of Medicine, Kingston, 1892, M R C S., England, 1892, aged 68, died, February 10

William R Roberts, Palestine, Texas, Meharry Medical Department of Central Tennessee College, Nashville, 1892, aged 68, died, February 25, of heart disease

Charles Bruehmann, St Louis, Washington University School of Medicine, St Louis, 1896, aged 62, died, March 15, in the City Hospital, of heart disease

William C Miller, Labadie, Mo., Beaumont Hospital Medical College, St. Louis, 1899, formerly county coroner, aged 60, died, March 12, of uremia

Richard Welch Lang ♂ Mount Lebanon, Pa., University of Pittsburgh School of Medicine, 1921, aged 40, was found dead, March 19, of heart disease.

George Lee Major, Fulton Ky., Vanderbilt University School of Medicine Nashville, Tenn., 1886, aged 79, died, March 9, of cerebral hemorrhage

Ephraim Derbyshire, Kissimmee Fla., Medical College of Indiana Indianapolis, 1881, aged 89, died, March 10, of aneurysm of the abdominal aorta

Newton Rector, Hennessey Okla., University of Nashville (Tenn.) Medical Department, 1874, Civil War veteran, aged 96, died, March 16, of pneumonia

Paul W Brossman, Womelsdorf, Pa., Temple University School of Medicine Philadelphia 1924, aged 36, died, March 10, of a self-inflicted bullet wound

Anson Scott Donaldson, Vancouver B C., Canada, McGill University Faculty of Medicine Montreal, Que., 1901, aged 58, died, March 17, of pneumonia

William Wallace Shriner, Cincinnati (licensed in Ohio in 1896), aged 88, died, March 22, of arteriosclerosis, angina pectoris and cerebral embolus

Ezra Warren Homiston, New York, Bellevue Hospital Medical College New York, 1883, aged 75, died, March 15, of carcinoma of the prostate

Fred L Potts, Vanceboro N C., Medico Chirurgical College of Philadelphia 1899, aged 61, died, March 23, of a self-inflicted bullet wound

Correspondence

CHRONIC VAGINITIS AND ACNE

To the Editor—In regard to the communication of Dr Arthur G Schoch in *THE JOURNAL*, March 9, page 852, concerning the "specious conclusion" that the acne was connected with the chronic vaginitis in my report of a case of chronic vaginitis treated with phenylmercuric nitrate (*THE JOURNAL*, January 19, p 212), much could be said. When the acne first appeared, the patient was told that it might be connected with the vaginitis, and that it might clear up if the vaginitis could be cured. That the two were connected I have no doubt from what actually happened, as recorded. The possibility of the acne being caused by the local applications of iodine was not even considered for the very good reason that it was present before the iodine applications were made. Moreover, at no time did the patient take iodine in any form (including iodized salt) by mouth. Again, at her age, the long lasting acne of adolescence did not have to be considered.

As in the case referred to by Dr Schoch, I have never seen acne due to iodine fail to clear up shortly after removal of the cause. I have had quite a number of cases, especially of chronic appendicitis, in which associated acne resisted treatment for a long time until sources of chronic infection were removed. Notwithstanding other opinions that differ from my own, I regard acne as being a manifestation of some systemic condition until the contrary is proved.

As I reported a case of vaginitis not of acne, it was not stated in the article that, aside from the use of the autogenous vaccine, the treatment of the vaginitis was paralleled by treatment directed at bettering the condition of the patient's skin, but it was stopped at least two years before the case came to a climax because as was expected in the presence of the vaginitis, it proved to be useless. Even phenylmercuric nitrate, the most potent and generally satisfactory antiseptic I have ever used failed in a 1,500 ointment. Roentgen treatments were purposely not used for reasons that need not be stated here. The vaccine injections did give temporary relief, but the acne did not show continued and increasing improvement until after the vaginitis had stopped. At the present writing, all I claim is that the vaginitis is cured, and the acne is still arrested to a point at which at least the patient considers it to be cured.

FREDERIC WADE HITCHINGS, M.D., Cleveland.

IODIZED POPPY-SEED OIL IN VENOUS SYSTEM

To the Editor—The instructive and interesting case report by Dr Geza Weitzner (*THE JOURNAL*, February 16 p 545), wherein is described accidental escape of iodized poppy seed oil into the venous system of the uterus during the course of an intra-uterine injection, suggests the following comments.

In an attempt to explain the etiology of such accidental venous roentgenograms, Dr Weitzner rejects the possibilities of 'excessive pressure during the injection' and 'pathologic permeability of the uterine vessels' in favor of the theory that supposes the presence of 'injury to the uterine wall' with probable invasion of the venous sinuses. The latter mechanism is substantiated, in the case of Dr Weitzner's patient, by the report of vaginal bleeding during four days immediately following the uterine manipulation. More direct evidence for such an explanation was given by Dr John A Sampson before the forty-third annual meeting of the American Gynecological Association on May 16, 1918, in Philadelphia (*Am J Obst* 78 161 [Aug] 1918). In a series of experimental roentgenograms of uteri that had been removed at operation and injected

with bismuth solutions, Dr Simpson described his surprise at the occurrence of complete visualization of the uterine venous system in an injected, myomiotons uterus removed during an episode of active metrorrhagia. This led him to experimental roentgenograms with uteri that were curetted, and in every such instance he obtained pictures of the uterine venous circulation.

In the discussion that followed Dr Sampson's presentation, Dr J Wesley Boice stated that he had discarded intra uterine injections of iodine after finding the injected solution in the venous channels of two uteri removed at operation.

This seems to lend weight to the opinion of Dr Weitzner

S LEON ISRAEL, M D, Philadelphia

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

DETECTION OF ALBUMINURIA

To the Editor—Please tell me the best and most sensitive qualitative test for albuminuria and the second best test with procedure for making tests and strength of solutions used. Will pus in an otherwise normal urine give a positive test for albumin and in what quantity before it will show? Please omit name.

M D Alabama

ANSWER—Normal urine contains a trace of albumin too slight to be detected by the simple tests in general use. All tests for albumin in urine depend on its precipitation by chemical reagents or coagulation by heat. These agents precipitate both serum albumin and serum globulin. Mucin or other constituents such as pus cells may give a reaction with some reagents. Pus cells in moderate numbers always give a faint positive reaction. Hence the urine tested should be clear and should be filtered if necessary. Many bacteria, especially when dissolved in an alkaline urine, may yield faint traces of albumin.

Usually simple filtration through a double layer of filter paper is sufficient. The bacteria may be removed by centrifugation or by the addition of a small amount of animal charcoal and shaking and filtering.

There are a dozen or more tests for albumin in the urine. These will be found in most books on laboratory technique or urinalysis. Three of the most reliable and simple tests are Exton's test, Purdy's test and Robert's test.

Exton's test 1 Filter the urine or remove the upper portion after centrifuging. 2 Mix equal volumes of urine and reagent in a test tube. The ingredients of the reagent are sodium sulphate, 200 Gm. sulphosaheyllic acid, 50 Gm. water to make, 1,000 cc. Dissolve the sulphate in 700 cc of water with heat, allow to cool, then dissolve the acid without heat and dilute to 1,000 cc. 3 If cloudiness does not develop albumin is absent. 4 Should cloudiness develop warm slightly over a flame. Do not boil. Any cloudiness that persists is due to albumin. 5 If the urine is slightly cloudy and cannot be cleared, the reaction should be compared with a tube containing water and urine. A distinct difference will be seen if albumin is present.

Purdy's test 1 Fill a test tube half full with urine. 2 Add about one-sixth its volume of saturated water solution of sodium chloride and from 5 to 10 drops of 50 per cent acetic acid. 3 Mix and boil the upper portion over a burner. Rotate while heating. 4 A cloud denotes albumin. This is a useful test, as the addition of the sodium chloride raises the specific gravity and prevents the precipitation of mucin. Bence-Jones protein may produce a cloud, which disappears on cooling.

3 Robert's test Place a few cubic centimeters of the reagent in a small test tube. Tilt and run clear urine from a pipet or dropper down the side to give a sharp line of contact. The reagent consists of saturated aqueous solution of magnesium sulphate 5 parts and concentrated nitric acid 1 part. If albumin is present, a white ring appears at the line of contact. This test is much more desirable than the Heller ring test using nitric acid. It is sensitive and eliminates the secondary colored rings due to indican, bile pigments, and the like.

DESCENT OF TESTIS

To the Editor—I have in my care a boy aged 10 years whose testicles have never descended. I can find no trace of them in the inguinal region or at the root of the penis. He is otherwise quite normal, bright and well nourished, the sixth in a family of eight. All the children are healthy. The father is an ordinary farmer. The patient is of a rather nervous disposition. He does well in school but is a little hard to manage at home. My object in writing to you is to be advised as to what if any measures are advisable in the case. I think he shows some indications though not definite of chorea. If nothing can be done will he be likely to go bad at puberty?

A C McGEE, M D, McNabb, Ill.

ANSWER—It is generally stated that sexual development in boys is slow between the ages of 9 and 12 and rapid between the ages of 13 and 15, slowing up again after the fifteenth year of age. The age of the onset of puberty varies with the various races. Testicular descent often occurs spontaneously during the period of most rapid sexual development in boys in whom a degree of cryptorchidism has been present.

From recent reports, the administration of the anterior pituitary-like gonadotropic stimulating substance from the urine of pregnancy has been advocated for the descent of the testes. When purely mechanical causes are obstructing the descent of the testes, this substance can have no effect. The age of the patient and his individual organ reactivity to the substance are variables to be considered in the treatment of any given case. If the treatment is given between the ages of 12 and 14, the result will probably be attained more effectively and more quickly than if treatment should be started at a young age period. The ages between 12 and 14 years may be considered the optimal period for successful treatment, because the normal developmental process at this time would cause a greater reactivity of the substance on the testis.

Besides the age of the patient, the dosage and the duration of treatment with the pregnancy urine extracts will be dependent on the degree of underdevelopment. The most favorable clinical responses have been noted at the age of early puberty.

Even though the boy is untreated, the testes may descend during puberty. If the testes fail altogether in descent and development, the patient will not "go bad," though he will suffer from sterility and a feminine habitus and mannerism.

PNEUMOCONIOSIS IN MOLDERS

To the Editor—I am gradually gathering a small series of cases of pneumoconiosis in molders who work in brass factories. There are six of them who within the past four years have worked in the foundry division. I would be interested to know if you have any information on the etiologic factor. I am informed that the molds are made of a special form of sand presumably silicon dioxide. The patients all lay their difficulty to the fumes that arise when the molten metal is poured into the sand molds. This is the only time to my knowledge when there is any large amount of foreign material in the atmosphere of the foundry. Please omit my name.

M D Michigan

ANSWER—Pneumoconiosis is a characteristic occupational disease of foundry workers. Sand blasting operations, shake-out work and sand conditioning, among other foundry activities, contribute dustiness to the atmosphere breathed by workers. Mold materials are high in silica (SiO_2) but some combined silicon may be present as silicates. Crypto-crystalline silica (tripoli) may be present in mold facing materials. Although free silica, this tripoli form is regarded as less harmful than ordinary silica, possibly because of its electrostatic properties, which hamper general atmospheric dustiness from this source. The x-ray picture of typical silicosis is characteristic in the presence of history of exposure. Other forms of pneumoconiosis are less characteristic but are suggestive. Roentgen examinations of the chest are desirable for dust exposed workers in the plant described, also dust counts. If proof of true dust lung disorders is established from roentgen examinations and if dust counts yield results indicative of concentrations of siliceous dusts in amounts above tolerable limits, unfailingly steps toward the elimination of dust hazards will be in order. During the last three years an extensive mass of technical information on dust hazards in foundries, silicosis in foundries, and protection against dust hazards in foundries has been published. Some such information appears in various issues of the Foundry, a trade publication edited in Cleveland, in the publications of the National Safety Council, Chicago, and in a booklet entitled "Silicosis in the Foundry," prepared by Dr. Carey P. McCord for the National Foundry Association (29 South LaSalle Street, Chicago) and published by that organization.

The patients' association of their difficulties with the immediate time of pouring metal probably has nothing to do with the pneumoconiosis. At that time, however, zinc and copper

fumes are given off, which may cause another characteristic occupational disease of the brass founders trade, namely, "brass chills," "zinc chills," "brass founder's ague" or "metal fume fever." The second type of occupational disease is much less significant than the first but much more obvious. The patient after exposure quickly may develop a mild respiratory tract inflammation, severe chilling, insatiable thirst, malaise and temporary depletion. It seems definite that little or no direct connection exists between the two conditions discussed.

SNAPPING OR TRIGGER FINGER

To the Editor—A woman aged 55 in good health has for the last ten years been affected by a condition of spastic flexion of the right ring finger. The condition follows hand work such as washing clothes and is becoming worse so that on the last occasion she could not extend the flexed finger with the other hand and there was excruciating pain in the palmar surface just anterior to the metacarpophalangeal joint where the flexor tendon was very tender and held in rigid spasm unlocking after several hours of hot soaking manipulation morphine and atropine. What is the likely diagnosis and treatment? Please omit name.

M D Massachusetts

ANSWER—The patient probably has a so-called snapping finger, or trigger finger. The condition results from either a bulbous thickening of the flexor tendons just distal to the proximal end of the digital sheath or a narrowing and constriction of the proximal end of the sheath itself opposite the metacarpophalangeal joint. The result of either of these conditions is obstruction to the free gliding movement of the flexor tendons. When the patient attempts to flex the affected finger it remains in extension until sufficient force is applied to draw the enlarged tendon through the narrowed sheath. This movement is often accompanied with a jerk or snap. When the patient subsequently attempts to extend the finger, this action becomes difficult because the bulbous enlargement interferes with the downward (distad) movement of the affected portion of the tendon, in other words, the same events take place in a reversed order.

The condition results from a sudden trauma or strain with partial rupture of the tendons, from inflammatory disease, which causes localized enlargement and thickening of the tendons, and from a number of other less common causes. It can usually be completely relieved by opening the narrowed sheath opposite the metacarpophalangeal joint and excising sufficient of the ringlike constriction to permit the tendon to glide freely back and forth.

PURPURA HAEMORRHAGICA

To the Editor—Recently I have seen a case of purpura haemorrhagica in a child aged 4 years. The previous health was good. There was no familial history of any blood dyscrasia. The child recovered within two weeks and has had no recurrence in a period of almost two months. The child had been given Dr. Jaynes Vermifuge combined with castoria a short time before the onset of the disease. I believe this case to be one of the secondary purpuras and wish information concerning the possibility of this vermifuge acting as an etiologic factor.

M D Arizona

ANSWER—Purpuric manifestations with thrombocytopenia have been noted following the ingestion of drugs to which the patient has an idiosyncrasy. The drugs present in this vermifuge have not been reported as producing such an effect but it would be instructive to investigate the possibility in this patient. The investigation could be carried out by doing a patch test or injecting a minute amount intradermally in dilute solution. One must bear in mind, however, that true essential thrombocytopenic purpura may appear suddenly and be effectively treated by blood transfusions. In such cases the patient may be free from symptoms for months or years, during which time there is no objective evidence of the disorder. In the absence of a demonstrable drug idiosyncrasy this case should be carefully followed as a potential case of Werlhof's disease.

TREATMENT OF GUMMA

To the Editor—Which of the two act more rapidly on a gumma the iodides or the arsenicals? Is the Herxheimer reaction the result of rapid and incomplete reaction? Please omit name.

M D Louisiana.

ANSWER—In treating a tertiary syphilis one finds that the action of the arsenical is more rapid than that of the iodides. The Herxheimer reaction is explained as follows. When a patient with syphilis, either in the early stage or with a gumma has had no treatment for the disease and gets his first injection of an arsenical there is a resultant edema of the localized lesion. The lesion becomes much more prominent, in the case

of early syphilis it will take on a bright red coloration but, naturally, with a tertiary lesion this will not be the case, and then the lesion begins to shrink in size rapidly. It is explained on the theory that the arsphenamine comes in contact with the spirochetes, causing their disintegration, that toxins, if there are any, are released from the broken down organisms, and that these cause an increased flow of blood to the part, causing the brightened color and localized edema. As a result of these toxins being released into the blood stream, often within the first hour or so after the arsenical injection the patient will have a high temperature. As a rule the Herxheimer reaction is seen only after the first injection of an arsenical. Of course, this reaction had been previously noted when mercury preparations were employed but of course the action was not of the sudden type seen after the arsenical therapy. One also may see a Herxheimer reaction after the first injection of a bismuth compound, provided no other previous antisyphilitic treatment has been given.

MENISCUS SIGN OF CARMAN IN GASTRIC CARCINOMA

To the Editor—What is the meniscus sign of Carman in regard to ulcerating carcinoma of the stomach?

L A CROWELL JR M D Lincolnton N C.

ANSWER—Carman, in urging the value of palpatory approximation of the gastric walls during fluoroscopic examination, laid stress on this technic as a means of showing abnormalities of the anterior and posterior walls. Compression of the walls with thinning of the layer of opaque ingesta can be accomplished most conveniently by slow stroking movements of the fingers downward over the stomach during the process of filling. It is important to do this before the stomach is fully distended, especially is this true in stout persons with excessively thick abdominal walls. During this manipulation, tumors on the posterior wall appear on the screen as translucent areas within the gastric silhouette, corresponding in size and shape to the growth. The crater of an ulcer appears as a dense, more or less circular spot, if it is possible to turn the patient so as to obtain an oblique or transverse view, a projecting niche may be noted. In the anteroposterior projection, when the walls are approximated as described an ulcerating cancer usually shows a central opacity representing the ulcer crater filled with barium within an encircling translucence, which corresponds to the surrounding infiltrated margin, and outside of this the diffuse density of barium in the stomach. As a rule, according to Carman, the concavity of an ulcerating cancer does not extend into or beyond the gastric wall, so there is no projecting niche at any angle of view. Absence of a niche and the presence of the three shadow zones are valuable signs of malignant ulceration in the stomach.

SOLUTIONS FOR USE IN EYE

To the Editor—When using hypotonic solutions for eye treatments (for example 0.125 per cent pilocarpine) patients will complain of disagreeable stinging sensations which are eliminated by adding 1.5 per cent boric acid. Is there a marked advantage in the hypotonic solution because of more rapid and more complete absorption? Must the hydrogen ion concentration be considered in routine eye solutions? Should eye solutions be considered as two groups—those with conjunctival effects and those with intralibular effects? Where can I find detailed information about these questions? Please omit name.

M D Pennsylvania.

ANSWER—There is in general no advantage in using hypotonic solutions of the alkaloids in distilled water. The addition of boric acid does not lessen their effect. It does give them an acid reaction, however, and an even less irritating form in which to dispense some of the common alkaloids is in a buffer solution of pH 7.6. Physostigmine in such a solution turns pink, but its absorption and effectiveness have been found in no way diminished. Such a buffer solution was described by S. R. Gifford and R. D. Smith in the *Archives of Ophthalmology* (9 227 [Feb.] 1933) and another article on the same subject will appear in the *Archives* shortly.

A buffer solution of reaction approximately pH 7.6 may be made of anhydrous boric acid 6.2 Gm., potassium chloride 7.4 Gm. and distilled water 1,000 cc. To 50 cc of this solution, which has a reaction of pH 5.5, is added 1 cc of a solution of sodium carbonate, 21.2 Gm. to 1,000 cc. of distilled water. This is suitable for atropine, homatropine, physostigmine and pilocarpine. The use of other buffers for other alkaloids is described in the articles referred to.

In *A Handbook of Ocular Therapeutics* by Gifford, published by Lea & Febiger, will be found a discussion of various drugs used for effect on the conjunctiva and those depending on absorption into the eye.

ALLERGIC REACTION AFFECTING EARS

To the Editor—A boy baby aged 18 months not irritable perfectly well prior to the onset of the present illness has had marked swelling of both ears of two days duration. Both ears stick out from the side of the head the same as in acute mastoiditis. There is an effusion of blood beneath the skin along the outer border of the auricle of both ears. They are very tender to touch and they feel warm. On the buttocks are several large reddish raised areas from 1 to 2 cm in diameter. One similar area appears on the inner aspect of one knee and the dorsum of the foot. What I should like to know is how could the two ears be affected at the same time? There is no history of a blow or external violence. The weather has been warm it being summer. The ears remind me of cauliflower ears of boxers. I would appreciate suggestions as to etiology. Please omit name. M D New York

ANSWER—There are several conditions that must be considered in the diagnosis of the ear lesions. Associated with the lesions on the buttocks, knee and foot, one might consider an urticaria, insect bites, dermatitis venenata or a purpura, in the winter, frost bite. The history states that external violence or injury can be excluded. Herpes zoster oticus of the external ears has been described, though the description of the lesion does not fit this condition.

Perhaps careful inquiry would aid in determining any dietary cause for an urticarial etiology of the condition or whether the child had been in contact with any plant that could possibly produce a dermatitis venenata. In case of insect bite one might be able to see a minute central puncture point. The external ear reacts to slight injury by swelling and redness often out of proportion to the exciting cause.

KELOIDS

To the Editor—A white woman aged 52 wishes the removal of a sebaceous cyst of the scalp region. The cyst is almost in the midline about $1\frac{1}{4}$ inches anterior to the union and about the size of a hickory nut. It is not very conspicuous and can be fairly well covered by the hair but at times causes itching and when the patient combs her hair it becomes irritated. I have advised excision but hesitate somewhat because of the susceptibility of the patient to keloid formation. Do you know of any means of preventing keloid or successful treatment after its formation? Please omit name. M D Wisconsin

ANSWER—The most satisfactory preventive of keloid formation in such a case is the exposure to x-rays before surgical removal and again afterward over a period of some weeks or, perhaps, months if evidence of keloid develops.

The results of treatment after a keloid has developed vary. Excision combined with roentgen therapy before and after may be necessary, but complete success should not always be expected.

The method and amount of roentgen therapy should be left to some one of experience and responsibility.

TUBERCULOUS ADENITIS

To the Editor—Will you be so kind as to send me the technic for roentgen therapy of tuberculous adenitis (cervical) in an infant. I wish especially to know the number of roentgens with an effective wavelength of from 0.210 to 0.218 angstrom unit to give in these cases.

JAMES P. MCGUIRE, M.D. Chicago

ANSWER—An effective wavelength of approximately 0.210 angstrom unit is furnished by 140 kilovolts, pulsating current, with a filter of 0.25 mm of copper and 1 mm of aluminum. In the case of an infant with tuberculous cervical adenitis the dosage should be about 75 roentgens once in three weeks over a period of three or four months. There is no danger to epiphyseal centers or to any of the normal glandular structures from such a dosage. It has been found efficient.

INJECTION OF CYST FOR ROENTGENOGRAPHY

To the Editor—I have a patient with what seems to be a branching enous cyst in the right side of the neck on a level with the vocal cords. The cyst contains sterile clear serum. I wish to inject a fluid that mixes well with serum and then make a roentgenogram to determine the extent of the cyst. Would tincture of iodine diluted be suitable? If so what strength? Would 10 per cent sodium iodide be concentrated enough to cast a good shadow and if not could tincture of iodine be added to the sodium iodide? What other solutions and strengths would you suggest? Please omit name and address. M D Pennsylvania

ANSWER—Tincture of iodine should not be used for injecting such cysts, as it may prove quite irritating or even toxic. Sodium iodide in 15 per cent solution gives a good shadow but occasionally may prove slightly irritating and should be aspirated after its use. Sodium bromide in 25 per cent solution gives a good shadow with little reaction but may be a little concentrated to inject through a fine needle. Iodized poppy-

seed oil is one of the least irritating of the contrast mediums but is quite viscous. Several similar and satisfactory proprietary preparations may be obtained. Neo-topax or any of the contrast mediums used intravenously for urograms may be used for this purpose. This will give a good shadow in a dilution of 1:3 with sterile distilled water. The sodium iodide and bromide solutions may be easily made up and sterilized, while the others or satisfactory substitutes may be obtained from any of the medical supply or pharmaceutical houses.

ADIPOSIIS DOLOROSA

To the Editor—A woman aged 39 complained of pain in the outer aspect of both thighs and considerable enlargement of both legs from the ankles to the hips which condition developed five years ago during her last pregnancy which was normal. Physical examination revealed a marked nonedematous enlargement of both legs with no abnormal increase in size above the hips. Both knee jerks were hypotonic. The blood pressure was 142 systolic 80 diastolic. Hemoglobin was 88 the red cell count was 4,600,000 and white cell count 7,800 with a normal differential. The basal metabolic rate was -2. A gain in weight from 140 to 216 pounds (63.5 to 98 Kg) was reported. A diagnosis of Dercum's disease or adiposis dolorosa was made. The patient had been treated with pituitary 1 grain (0.065 Gm) daily for eleven months and this was followed by thyroid 2 grains (0.13 Gm) daily for the past five months. There has been no loss of weight and the condition has remained the same. Is there any accepted treatment for adiposis dolorosa? I would appreciate any suggestions regarding this case.

H. H. BURROUGHS, M.D. LeMars Iowa

ANSWER—There is no effective treatment for adiposis dolorosa. If the fatty masses are painful, salicylates or other analgesics may be given. If the fatty masses are not tender massage may be tried. Continuous warm baths and a restricted diet may have some effect. Thyroid is worthy of a trial. From the description of the case it is difficult to tell whether it is one of adiposis dolorosa or whether one is dealing with pituitary basophilism, trophedema or progressive lipodystrophy.

NODULATION OF EPIDIDYMIIS

To the Editor—Is there any method of removing nodulations of the epididymis that followed an epididymitis i.e. without surgery or is there any harm in leaving these nodules untreated? Kindly omit name.

M D Illinois

ANSWER—As a rule, nodules in the epididymis disappear in due course of time. As an aid to clearing up these nodules the use of heat in the form of hot wet dressings twice a day is valuable and the internal administration of potassium iodide with sodium salicylate is advisable. If the nodules do not completely disappear and they produce no symptoms, there is no harm in letting them alone.

However it is important to rule out the possibility that the nodules are due to tuberculosis, and a careful examination of the prostate, seminal vesicles and vas deferens is in order to rule out this possibility. With this out of the picture, the foregoing line of treatment may be followed.

BLEACHING OF PIGMENTED SKIN

To the Editor—Is there a formula you can suggest for the removal of a darkened portion of the skin i.e. of the neck? Please omit name.

M D New York

ANSWER—The patient should be studied for possible endocrine disturbance. Cases of hyperpigmented skin have been found due to insufficiency of the ovaries, thyroid or pituitary and have been relieved by treatment with extracts. If no such condition can be demonstrated, local treatment may be tried by combining perhydrol 1 part, a 30 per cent solution of hydrogen dioxide anhydrous wool fat 6 parts and petrolatum sufficient to make 10 parts. This should be applied to a small area once a day. If irritation results, one should cease the application and wait for the reaction to subside. If no result is obtained the strength of the perhydrol can be cautiously increased. After a small area is bleached somewhat the next area may be treated until a satisfactory result is obtained.

TABETIC PAINS

To the Editor—In reading Queries and Minor Notes in THE JOURNAL, March 30 page 1188 I was interested in your reply to M D New York, concerning the treatment of tabetic pains. Your answer contains no reference to any form of intradural therapy. In my own experience since the publication of my article in 1914 I have repeatedly found that the subdural administration of mercurialized serum (one-fiftieth grain or 0.0013 Gm of corrosive mercuric chloride) is particularly efficacious in relieving the tabetic pains. I rarely find it necessary to give more than four treatments and often two are sufficient.

C. M. BYRNES, M.D. Baltimore

Book Notices

The Brain as an Organ Its Postmortem Study and Interpretation By Frederic Wertham M D Assistant Professor of Psychiatry New York University Bellevue Hospital Medical College and Florence Wertham With an Introduction by Adolf Meyer M D Psychiatrist in Chief Johns Hopkins Hospital Baltimore Cloth Price \$7 50 Pp 538 with 166 Illustrations New York Macmillan Company 1934

It is probably more unusual for a neurologic monograph to inspire enthusiasm than for any other type of book, yet the present work is distinctly one of the most stimulating of its kind to have appeared during the last few years Two years ago, with the exception of a small British monograph, no good systematized volume on neuropathology was available in English During the spring of 1933 this condition was rectified by the publication of three excellent volumes on neuropathology, but they were textbooks, systemic presentations describing in particular the microscopic appearances of the structures attacked by disease processes abusing the central nervous system. But the Werthams have produced something more than this They have produced a thick volume which synthesizes the known facts concerning nervous system pathology so that the whole mass of seemingly uninteresting and inconclusive facts treating of the subject is logically rearranged to have meaning Isolated chapters are impressive in their completeness for instance, that dealing with technical methods is entirely satisfactory One who wishes to use this book as a reference for all neuro pathology, to look up, for instance, "disseminated sclerosis" will be disappointed, for although this disease is mentioned innumerable times a simple description cannot be found, possibly because the authors presume considerable background on the part of the reader Of psychiatric entities the situation is different, alcoholism, dementia paralytica and senile changes are all covered sensibly and comprehensibly In other words "How does it look?" is neglected for "What is it all about?" Two criticisms can be deduced First, although many researches are referred to during the various discussions, just where reports of these studies can be found is seldom noted, and the bibliography is weak because of its generality For the casual reader and the well equipped researcher, this consideration is not serious, but beginning specialists in the field will want to turn to this volume early and will miss careful annotation. The care with which the book is written and the style, superior to that of many technical works, will be the reasons for the beginner's interest The second criticism to be made is the authors' failure to admit of a chemical pathology (in schizophrenia particularly) undemonstrable as yet anatomically The last chapter treating of forensic histopathology, is a contribution in itself, revealing medicolegal uses undreamed of by those

who have not yet had to face these special problems but which should be known to all psychiatrists. About a fourth of the book is made up of histologic drawings excellently reproduced by the aquatone process, all of which are original and are contributions of no mean order to the text. The book is highly technical.

Alcohol and Anesthesia. By W. Burrill D.M. M.A. Professor of Physiology, Lucknow University. Cloth. Price 2/6. 1 p. 63 with 1 illustration. London: Williams & Norgate Ltd. 1931.

In this booklet the author advances an explanation of the effect of ethyl alcohol on a heart perfused with Ringer's solution, with and without the admixture of the alcohol. He shows that the functional capacity of the heart can be both depressed and stimulated by the alcohol and also both stimulated and depressed by removal of the alcohol. He suggests that the energy content of a muscle available in adsorption phenomena be called 'kinesiphore A,' and that the energy available in the colloidal aggregation state be called 'kinesiphore B.' He maintains that alcohol decreases the muscular or nervous excitation energy derivable from kinesiphore A and increases that which is derivable from kinesiphore B. He philosophizes concerning the mind and how it functions normally, abnormally and under the effect of alcohol. He discusses chronic alcoholism and suggests that the abuse of alcohol for a long period artificially supports the individual, permitting some of his glands of internal secretion to undergo some degree of atrophy from disuse. He mentions some other drugs the action of which seems to have become controversial, and he finally discusses anesthesia from the standpoint of the manner in which anesthetics may affect the individual, utilizing the theories that he has developed from his notion of how alcohol affects an individual. He suggests that the central neurons of the nervous system are ever in rhythmic activity and that this rhythm is disturbed by the anesthetic, and he goes on to explain as many of the phenomena of anesthesia as are usually explained by the theories, or more of them than are so explained, for example, the effect of local and general anesthetics, ether convulsions, postanesthetic psychosis, sudden death in the course of anesthesia and absence of relaxation. The text is well written, fifteen references are given and an index is supplied. The essay will interest all who use alcohol or anesthetics.

Health Education in Senior High Schools. A Study of the Qualifications, Status, Affiliations and Functions of Persons Responsible for Health Education in Senior High Schools with Special Reference to New Jersey. By Dorothy Ruef, Ph.D. Teachers College, Columbia University. Contributions to Education No. 636. Published with the approval of Professor Jesse F. Williams, Sponsor. Cloth. Price \$1.50. Pp. 106. New York: Bureau of Publications, Teachers College, Columbia University. 1934.

This monograph is a factual study of health education in senior high schools in New Jersey. It deals with organization and personnel, health education activities, faculty relationships, external relationships of the school and personnel, and professional history of teachers in health education. The state of New Jersey has a law requiring the teaching of health education, and the New Jersey State Department of Public Instruction is in charge of such teaching. It might therefore be supposed that health education in New Jersey high schools would be in a reasonably advanced state. The study shows that conditions in New Jersey, which are probably typical of conditions in other states, leave much to be desired. There is no uniformity of plans or of organization and there is a great variety of personnel. For example, physicians, dentists, registered nurses, physical education teachers, health education teachers, home economics teachers and general science teachers not only participate in health education activities but head the departments. The lack of coordination and uniformity revealed by this report is no surprise to those who are familiar with the new art, for it is not yet a science of health education. The necessity for teaching health has been recognized rather universally, but it has not yet been possible to devise and procure adoption or even trial on any large scale of acceptable plans and programs for meeting the necessity. Even more important, it has not yet been possible to furnish trained personnel for the teaching of health. It is a difficult decision under such circumstances whether it is better not to attempt health teaching at all or to attempt it under unfavorable circumstances with unprepared though sincere personnel. There is grave liability

that harm may be done by the untrained. There are plenty of teachers capable of teaching who have not the necessary factual material for health teaching, and there are plenty of doctors untrained in pedagogy who do have the factual material. The problem is how to combine the necessary educational qualifications with the requisite scientific information. This report, bringing out the facts in a definite and organized manner, should be of considerable help in throwing light on the problem in New Jersey and secondarily in other states with which the New Jersey situation may be compared.

Handbuch der experimentellen Pharmakologie. Herausgegeben von A. Hoffer. Fortgeführt von W. Heubner. Professor der Pharmakologie an der Universität Berlin. Band III, Teil 3. Chrom-Metalle der Erdsäuren (Vanadium-Niobium-Tantal)-Titanium-Zirkonium-Zinn-Blei-Cadmium-Zink-Kupfer-Silber-Gold-Platin und die Metalle der Platingruppe (Palladium-Iridium-Rhodium-Osmium-Ruthenium)-Thallium-Indium-Gallium. Paper. Price 78 marks. Pp. 1593. 2188 with 87 illustrations. Berlin: Julius Springer. 1934.

This part of the third volume deals with the metals chromium, vanadium, zirconium, tin, lead, cadmium, zinc, copper, silver, gold, platinum, palladium, iridium, rhodium, osmium, ruthenium, thallium, indium and gallium. Aside from the intrinsic interest in a discussion of the action as far as it is known, of so many of the rarer metals, regarding which it is difficult to secure information anywhere else, the chief emphasis of this volume is on lead and most especially its toxicology. It is pointed out in this chapter that, in spite of the 'optimistic' report regarding the harmlessness of the traffic in ethyl gasoline of the American and the British commission, it is advisable to reserve final judgment most especially in view of progressively increasing employment of this product. One of the first symptoms of poisoning by it is insomnia. The ubiquitous use of lead in modern industry renders lead a disease of civilization. It is not quantity but constancy of ingestion that leads to damage, just as it is 'constant dropping that wears away the stone.' Lead like syphilis may affect any and all the organs of the body of any one with known or unknown exposure. Hence a suspicion of the possibility of plumbism should accompany the traditional suspicion of the presence of syphilis in every patient presenting himself for treatment. There is need therefore, of a test for plumbism quite as specific as the Wassermann test is for syphilis. This is found in the increased amount of lead in the blood and the excretions, tests for which are given in detail. The treatment is discussed from the experimental and clinical standpoint with the conclusion that the rational therapy of plumbism is still at the beginning of its development. One cannot help hoping and wishing for the speedy issuance of the final sections of the handbook and the publication of the index to act as the 'open sesame' to this vast treasury of information on pharmacology.

Tuberculosis. A Book for the Patient. By Fred C. Holmes, M.D., Director of the National Tuberculosis Association. Cloth. Price \$2. Pp. 312. New York & London: D. Appleton Century Company Inc. 1935.

Every one who has had a tuberculous patient knows the innumerable questions they ask concerning their own cases and the disease in general. Dr. Holmes' new book comes at a time when there is a dearth of suitable material with which to supplement one's advice and answers. Its principal value lies in the second half which is devoted largely to special methods of treatment such as artificial pneumothorax, operations on the phrenic nerve and thoracoplasty. He gives the patient a clear conception of each of these procedures and treats them fairly with regard to advantages and disadvantages. He calls attention to the importance of careful and complete examination and the significance of definite diagnosis by modern methods. The general treatment consisting of cooperation of the family, rest and diet, are discussed in detail. The physician should read the book himself before recommending it to his patients, both for the information it may add to his own store of knowledge and so that he can call attention to some questionable statements. In view of the fact that so much has recently been written in the American literature concerning the decrease in the incidence of positive tuberculin reactors, a question doubtless will arise in the minds of many readers concerning the statement that every one becomes infected with tubercle bacilli and therefore reacts positively to the tuberculin test. To be sure, the number of persons reacting positively to the

tuberculin test varies in different parts of the country and even in different parts of the same city. Dr Holmes's statements in this respect may be based on observations in his own community. Another statement is made to the effect that the mortality from tuberculosis has definitely decreased but that there has been little or no decrease in morbidity. This statement also may be based on local observations, yet in many parts of the country definitely reduced morbidity has been reported, notably Detroit. Many physicians will doubtless take issue with the statement that more than half of the infants infected during the first year of life and about one fourth in the second year of life develop fatal tuberculosis, since recent actual observations show that relatively few infected infants die of the disease while in infancy and childhood. Aside from a few statements of this kind, which after all are not serious, the book contains much valuable material that will be of definite assistance to the tuberculous patient and his friends, and even to the physician himself.

Die Haut und Geschlechtskrankheiten. Eine zusammenfassende Darstellung für die Praxis. Herausgegeben von Prof. Dr. Leopold Arzt und Prof. Dr. Karl Zieler. Lieferung 18/19. Band I. Haut und innere Sekretion. Von Prof. Dr. Julius K. Mayr. Haut und Stoffwechsel einschließlich der Ernährungstherapie. Von Priv. Doz. Dr. Erich Urbach. Vererbung und Hautkrankheiten. Von San. Rat. Dr. Leonhard Leven. Allgemeine Dermatologie. Von Prof. Dr. Leopold Arzt. Allgemeine Grundsätze und allgemeine Verfahren bei der Behandlung von Hautkrankheiten. Von Dr. Conrad Siebert. Physikalische Behandlung der Hautkrankheiten. Von Primarius Dr. Josef Kowarschik. Lichttherapie. Röntgen (Anhang). Röntgen Grenzstrahlen. Von Prof. Dr. Herbert Fuhs und Josef Konrad. Radium. Von Prof. Dr. Herbert Fuhs. Paper. Price 21.40 marks. Pp. 331. 684 with 228 illustrations. Berlin & Vienna. Urban & Schwarzenberg. 1934.

Die Haut und Geschlechtskrankheiten. Eine zusammenfassende Darstellung für die Praxis. Herausgegeben von Prof. Dr. Leopold Arzt und Prof. Dr. Karl Zieler. Lieferung 20. Band II. Kreislaufstörungen und Hämorrhagien der Haut. Von Prof. Dr. Heinrich Gotttron. Mechanische, chemische, thermische und aktinische Schädigungen der Haut. Von Prof. Dr. Leo Kumer. Paper. Price 12.60 marks. Pp. 1. 234 with 99 illustrations. Berlin & Vienna. Urban & Schwarzenberg. 1934.

These two volumes contain some interesting chapters not usually found in works on dermatology. Among the contributions are those of Mayr on the skin and internal secretions, Urbach on metabolic disorders, Leven on hereditary skin diseases, Arzt on general dermatologic morphology, Siebert on the general principles of therapy and their application, Kowarschik on physical therapy, and Fuhs and Konrad on phototherapy and on roentgen and radium treatment. In the second volume Gotttron takes up the circulatory disturbances and hemorrhages of the skin and Kumer the mechanical, chemical, thermal and actinic injuries. The articles are concise, well written, authoritative and accompanied by numerous excellent illustrations. They can be read with profit by all who are interested in clinical dermatology.

The Case for Sterilization. By Leon F. Whitney. Cloth. Price \$2.50. Pp. 309 with 1 illustration. New York. Frederick A. Stokes Company. 1934.

In this book the author, who is an ardent advocate of human sterilization as a means of controlling many of the social ills of our day, presents the history of this movement up to fairly recent times. He discusses the new German laws and describes the application of the law in those states of our own country which already have such legislation. His book fails, however, to recognize adequately many of the best arguments opposed to human sterilization. The book will serve, however, as a useful work for those who wish to make a beginning in their study of this problem.

A Psychiatric Word Book. A Lexicon of Terms Employed in Psychiatry and Psychoanalysis Designed for Students of Medicine and Nursing and Psychiatric Social Workers. By Richard H. Hutchings, M.D. Superintendent, Utica State Hospital. Fourth edition. Fabrikoid. Price \$1. Pp. 212. Utica, N. Y. State Hospitals Press. 1933.

The development of a new nomenclature in the field of neurology and psychiatry, particularly by the advances in the field of psychoanalysis, has made necessary repeated editions of this collection of the significant words that have come into that literature. In fact neurology and psychiatry are noted for their highly special diction. A word book of this type is useful to those constantly employed in this field. Most of the words are, however, available in the better medical dictionaries.

The Science and Practice of Surgery. By W. H. C. Romanis, M.A., M.B., M.Ch., Surgeon and Lecturer on Surgery, St. Thomas's Hospital, and Phillip H. Mitchell, M.D., M.S., F.R.C.S., Hon. Surgeon to H. M. The King. Volume I. General Surgery. Volume II. Regional Surgery. Fifth edition. Cloth. Price \$13 per set. Pp. 789, 962 with illustrations. Philadelphia. Lea & Febiger. 1934.

In the present edition of this extensive work, several chapters have been rewritten and the text in general reworded so as to bring it in line with more recent advances. Each chapter is preceded by a brief discussion of the anatomy and physiology of the region, which is adequate for the needs of the student. The authors attempted properly to lay the greatest emphasis on the surgical pathology. Operative procedures and technique are assigned a subordinate place. On the other hand, the after-treatment receives the attention it merits. The text is authoritative throughout, and the purely literary quality of its English adds not inconsiderably to its intrinsic value as a textbook. The weakest point of the work is to be seen in the illustrations, many of which represent not only far advanced but rather unusual pathologic conditions seen but rarely in the practice of the present age. Such illustrations are of no value in teaching surgical diagnosis.

French Medicine. By M. Laignel-Lavastine, Professor in the Medical Faculty in Paris, and M. Raymond Mollnery, Gold Medalist of the Academy of Medicine. Translated by E. B. Krumbhaar, M.D., Professor of Pathology, University of Pennsylvania. Clio Medica. A Series of Primers on the History of Medicine. V. Edited by E. B. Krumbhaar, M.D. Cloth. Price \$2.50. Pp. 187 with 14 illustrations. New York. Paul B. Hoeber Inc. 1934.

The great names of French medicine should of course be known to physicians everywhere. The contributions of Paré, Laënnec, Claude Bernard, Pasteur, Widal and Charcot rank with the greatest in all medical history. The present book is so concentrated as to give hardly adequate consideration to the work of any of these famous contributors. It does provide, however, references to a great number of lesser lights who also have aided in building the great medical structure. A section of special interest is the concluding chapter dealing with military, naval and colonial medicine, the author fails unfortunately to refer adequately to the excellent work of Nicolle.

A Textbook of Surgery. By John Homans, M.D., Clinical Professor of Surgery. Compiled from Lectures and Other Writings of Members of the Surgical Department of the Harvard Medical School. With a Special Bibliographical Index and with Illustrations by Willard C. Shepard. Third edition. Cloth. Price \$8. Pp. 1231 with 517 illustrations. Springfield, Ill. & Baltimore. Charles C. Thomas. 1933.

This volume represents the lectures given in the department of surgery at the Harvard Medical School. The third revision includes a considerable number of changes but without any necessity for change in pagination, because some of the material already in the book has been removed in each instance to make place for the new that is added. The volume is supplemented by an excellent bibliographic index, which includes references to original articles describing the surgical procedures. A statement on the jacket of this work indicates the principal subjects that have undergone correction, among others such topics as water balance and dehydration in surgery, the interpretation of abdominal pain, congenital obstruction, thoracoplasty, and tests of the peripheral circulation. This book is excellently written and most comprehensive. Its earlier editions met unanimous favor. The illustrations are unique for their clarity and uniformity.

English German and German English Medical Dictionary. By Joseph R. Waller, M.D., and Moritz Kautz, M.D. Part I. English German. English-Deutsches medizinisches Wörterbuch. Von Dr. Moritz Kautz. Fourth edition, edited by Dr. Adalbert Springer. Cloth. Price 6 marks. Pp. 201. Leipzig & Vienna. Franz Deuticke. 1934.

This is now in its fourth edition. While not a large medical dictionary, it provides an excellent selection of the words most used. It is in every sense of the word a dictionary compend rather than a contribution to medical etymology.

Nature's Way. The Fertile and Sterile Periods of Marriage. By Victor C. Pedersen, A.M., M.D., F.A.C.S. Cloth. Price \$1. Pp. 91. New York. G. P. Putnam's Sons. 1931.

This little volume is planned to supply the public's desire for an outline of the so-called fertile and sterile periods of marriage. Dr. Pedersen discusses the Ogino-Knaus researches and indicates their practical application.

Miscellany

OSTEOPATHY AND LICENSURE

FREDERICK ETHERINGTON, M.D.
KINGSTON, ONT

Talking of celebrated and successful irregular practitioners in Physick he said "Taylor was the most ignorant man I ever knew. Taylor was an instance how far impudence could carry ignorance"

—Samuel Johnson, 1779

I fear it may be thought a presumptuous procedure of 'carrying coals to Newcastle' for me to come from Canada to present a paper on the subject of 'Osteopathy and Licensure', for osteopathy is the ill formed child of lowly parentage—your child, not ours—which first saw the light of day sixty years since at Kirksville in the state of Missouri. With the passage of the intervening years, its unwished progeny have drifted across the international border to harass and annoy those of us concerned with medical registration.

As a member of the College of Physicians and Surgeons of Ontario, the sole body in the province empowered to license to practice medicine, my interest in this question was awakened when representatives of the cult put forward claims for further recognition, for according to our Drugless Practitioners' Act osteopaths, enrolled under their own board of regents, must confine their practice to manipulation and are not permitted to employ the designation "Doctor." Now they wished

- 1 To be empowered to sign birth and death certificates
- 2 The right to use the title 'Doctor'
- 3 The privilege of writing prescriptions
- 4 The right of entry to public hospitals
- 5 To have their services accepted by the Workmen's Compensation Board
- 6 The right to make use of public health laboratories

In pressing these large claims which to all intents and purposes constitute a demand to be admitted to medical licensure, these gentlemen repeatedly avowed that their schools of instruction in this country (there being none in Canada) maintained standards of admission and training equal to those of our regular schools of medicine. To examine the accuracy of this statement Dr Ryerson and I were delegated to visit some of your leading osteopathic schools and to report our observations.

While it is not possible in the allotted time to attempt a detailed examination of the so called theory on which the system is based, it is necessary for the present purpose to state in a general way the fundamental tenets of this cult, as gleaned from their authorities. They may be thus put down

- 1 The body is able to produce within itself all substances and materials necessary for the maintenance of health and for the prevention and cure of disease
- 2 Disordered circulation is the result of bony maladjustments, chiefly in connection with the spinal articulations. These maladjustments, or 'lesions,' by pressure on nerves, cause dysfunction in arterial supply and resultant disease
- 3 The chief, if not the only necessity in the cure of disease is the readjustment by manipulation of spinal luxations and impactions and, associated with this, the relief of muscular contractures

I have thought it wise to state the principles on which the system is based, for I feel they are not generally known to, or fully understood by, medical men. It is necessary in discussions of this kind to drag these grotesque beliefs from their

obscure lurking places and to expose them for a brief moment to the light of reason. For the majority of physicians on hearing these principles enunciated immediately lose patience with their palpable absurdity and refuse them further consideration. This reaction is understandable enough but I fear it is a mistake in tactics. Only by repeated exposures of the vacuous and absurd fallacy of the theory will the public mind become sufficiently informed to insist on legislation consonant with reality and truth.

It may be worth noting in passing that this entire and wonderful system is based on an experience of A. T. Still. Suffering one evening from headache, he left his house and went to sleep outside. Suspending a rope between two trees, he lay on the ground, rested his head on the rope and dropped off to sleep. When he awoke, marvelous to relate, his headache had departed! As if he were the first man to go to sleep with a headache and awake without one! In any event he attributed the result to relief of pressure on the upper cervical nerves. From this incident was osteopathy begot. Surely what purports to be a scientific system of healing was never before or since evolved from a hypothesis so slight, so feeble and so slender!

In submitting the portion of my paper about to follow, it is scarcely necessary to premise that I am not suggesting that the pressure of bone on nerve does not at times cause dysfunction, for neuritis and muscle atrophy so caused are not uncommon. On the other hand it is of interest to recall how frequently even excessive deformity of the spine occurs without producing accompanying disorder. To maintain by logic the thesis of the general causation of disease by mechanical agencies would appear to be a task of sufficient magnitude to dishearten the subtlest dialectician among the ranks of Still's disciples. Of supporting scientific evidence I have not been able to discover a trace.

To shoot holes in this flimsy construction were child's play indeed. At the Chicago school I asked the dean if he could produce a specimen to prove the 'back-bone' theory of disease causation. The reply was frank enough. He had none and he knew of none. The proof of the theory, he said, was based entirely on clinical results following osteopathic treatment.

Deferring for the present any reference to the conflict between the 'back-bone' theory of disease causation with the vast array of facts indisputably established by bacteriologists, let us glance at one or two hiatuses in the osteopathic concept where it presumes to account for the general occurrence of disease, as it must needs do if it is to warrant serious consideration. If pathologic states are the result of pressure by bony irregularities on spinal nerves, how does the osteopath account for disease in the central nervous system, as for example cerebral new growths and whence arise those many lesions found in the field of distribution of the cranial nerves? Obviously they cannot be caused by vertebral displacements. Again, if there be a constant cause at work, i.e. pressure the same type of disease should always be found in the distribution of a given nerve trunk. This does not occur, a fact that could be easily proved by the veriest tyro in pathology. If this practice has any foundation in fact, may I ask in the name of mercy, if not of utility, why faithful domestic animals on whose usefulness our comfort and indeed our very lives depend have not received during the past half century the benefits of its ministrations? Has any one ever heard of an osteopathic veterinarian? A dog in its illness is not subjected to futile and harmful manipulations, but if our legal safeguards are not kept intact a sick child may be submitted to treatment resulting in delayed recovery, deformity or death.

From a broader angle, how does the "back-bone theory" account for the innumerable diseases affecting that large division of the animal kingdom known as the invertebrates, and what of the diseases of plants? But why continue? Clearly this

empty theory is empiricism in its rankest form. It does not possess a single scientific prop to lean on, much less a leg to stand on.

If, however, osteopaths were to adhere to their tenets and were to practice their art according to their professed principles, there would be little ground for dispute or dissension. But when one visits their schools and finds them endeavoring to give more or less comprehensive courses in bacteriology, one is constrained to ask them: What have you to do with pathogenic bacteria? How do they fit into your scheme? Indeed, on two occasions I could not refrain from asking this very question, once of a teacher in his laboratory, once of the dean of the largest school. The former quickly gave his case away when he avowed his belief in the efficacy of diphtheria antitoxin. "It would be criminal," he said, "not to use it," while the latter explained that bacteriology was taught chiefly to enable students to pass state board examinations. A professor at a leading school acknowledged to my colleague that osteopaths accepted all proved theories of present-day bacteriology and used Zinsser's textbook. He said they advocated the use of antitoxin and serums for diphtheria, tetanus and rabies, and depended on the Dick and Schick tests. Asked to fit this in with the osteopathic belief as to causation of disease, he held that a person would be rendered less susceptible to infection by the use of osteopathic methods which, I submit, is mere quibbling and shallow subterfuge.

In a hearing before our provincial legislative committee the chairman, a lawyer more than friendly to the cult, asked one of its proponents "If you were treating a case of pernicious anemia would you administer liver?" "Certainly," came the immediate reply thus jettisoning in a single word this whole unsupported and unsupportable theory. The simple and obvious fact is that these irregulars aim not to practice osteopathy but to diverge from their limited and restricted field to embrace as far as their knowledge and training will permit the whole domain of medicine. As a recent editorial in the *London Lancet* observed, "It is in the fact that osteopaths have largely if not overtly receded from the doctrine enunciated by their founder, and have laid down a curriculum for their students including at least a smattering of most of the subjects taught to doctors, that the danger lies for the osteopath clearly wishes to induce the public to regard him as a healer equipped with adequate medical training." I take it for granted that no one here will deny there are a number of pathologic conditions, relatively few to be sure which yield to and call for, manipulative treatment.

The point I wish to make is this. While it may be granted for purposes of argument that these men may be skilled in certain remedial manipulative measures, of limited application their knowledge of and training in the fundamental subjects, which must form the basis of any general system of healing, are superficial and grossly inadequate. And further the systems of osteopathy and medicine are so utterly at variance that every means should be employed to keep them separate and distinct.

For the purpose of appraising the character, quality and value of the work done in schools of osteopathy, Dr. E. Stanley Rverson and I visited four of the leading centers.

Our conclusions were as follows:

1 The buildings, plant and equipment of the four colleges visited do not provide the facilities necessary for the training of students destined to practice any general system of the healing art.

2 Hospital and clinical facilities are entirely inadequate.

3 Requirements for admission and length of courses fall far below the standards maintained by the faculties of medicine of Ontario.

4 The curriculums and courses of study are so different from our own in their quality and fundamental principles of instruction that they could not in any sense be recognized as equivalent.

5 The scientific training and clinical experience of the teaching staffs are not of a quality or character to warrant their courses being accepted as fulfilling the requirements of the College of Physicians and Surgeons of Ontario.

6 As a result of our visit and after an inspection of their buildings, plants and equipment, their hospital and clinical facilities, their requirements for admission and their curriculums after attending some of their lectures, laboratory classes and clinics, and bearing in mind the lack throughout the course of any adequate bedside teaching, we are firmly convinced that it would be against public interest and welfare to admit the graduates of these schools, past or present to the Ontario licensure examinations.

If time permitted, I could marshal any number of observed and indisputable facts to substantiate these general conclusions but as time does not so permit I shall endeavor briefly to make some remarks on (1) anatomy, (2) pathology and (3) clinical training.

ANATOMY

With reference to the position of anatomy, I shall sketch what was seen in the best and in the worst of the four dissecting rooms the other two ranking midway between those here referred to.

In Philadelphia eighty students under four or five demonstrators, in a room measuring 68 by 32 feet were dissecting the dorsal region. We were shown a nerve with accompanying vessels emerging from a muscle. Names were not given nor connections referred to, for the teacher seemed chiefly interested in pointing out how engorgement of the vessels might well cause nerve irritation. Again, a dissection of the posterior abdominal wall in the lumbar region was used to show the possibility of nerve irritation by reason of psoas contraction. There were exhibited also several sacro iliac joints and the professor rather proudly demonstrated that the joint was lined with synovial membrane, a phenomenon he claimed to have observed on several occasions. And much more along the same lines.

One could not escape the conclusion that the purpose of the study was rather to bolster up the derelict theory of mechanical causation of disease than to attempt a serious consideration of the subject. With regard to the length of the course, we were told eight hours a week from December to June was required of first year students, with similar periods from September to December for the second year. Final examinations were not required from those whose term work was satisfactory, and of last year's class of eighty only five failed thus to qualify.

The annual announcement states "A notable collection of specimens and models is on display and arranged for study." These we asked for but failed to find, the sole specimen shown being a vertical section of a child's body. There was all but complete absence of the equipment usually a part of an anatomic laboratory.

The impressions carried away were that while the room was clean and orderly it was too small for the number of students the dissections were poorly done technically and were lacking in thoroughness and detail, the director, keen enough on his work, gave no evidence of a scientific point of view or comprehensive knowledge of his subject. Clearly the quality of the work was in no degree comparable to that required from our students of medicine.

Referring now to the other dissecting room I shall simply quote a note made at the time of the visit. "The culmination of our inspection was reached when we were escorted to the dissecting room. Situated in the back part of the basement was a dingy cellar-like room into which a little daylight filtered through small, dirty windows. There were six rusty iron tables four standing, two thrown into a corner along with some stools.

These constituted the complete equipment. Adjoining this room was a smaller one (10 by 16 feet) where there stood an uncovered vat filled with dark foul-looking fluid, said to cover four bodies. On a table was a body of a colored man, which appeared to have undergone partial decomposition. Altogether the place might aptly be described as a chamber of horrors. It seemed to brand not only the department of anatomy, if such a term could be employed, but the whole institution with an indelible mark of inefficiency and dirt. Des Moines is a clean-looking city. It must be that the municipal health officials are unaware of this nuisance."

PATHOLOGY

In this audience it will be taken for granted that there can be no scientific system of healing which is not broadly and soundly based on an extensive and accurate knowledge of pathology. So far as we could determine by observation and enquiry, pathology is "the forgotten man" of the osteopathic system. Indeed there is good reason why this should be for the whole problem is so delightfully simple. Disease is caused by spinal luxations. Thus pressure is exerted on nerve trunks and dysfunction follows. As the cause is simple and constant, the remedy is obvious. Therefore why worry about the resultant cellular manifestations those obscure and complex changes taking place in the tissues? This would seem to be the reasoning, and confirming this opinion we were not able to discover in any of the schools that the subject of pathology received study worthy of the name. Of the almost complete neglect of gross pathology there was ample evidence. The museums were primitive and from a teaching point of view all but valueless. A note made at the largest school read "on a table along one wall were some sixty glass jars of various shapes and sizes, containing specimens. As the jars were begrimed with dust, identification of the contents was difficult. Some labels read Aneurysm, Cancer of the Breast, Intussusception. There were a number of fetuses of different ages, among them being a monstrosity of a pig. In disorderly arrangement, the specimens preserved in formaldehyde were not mounted to show to advantage the pathologic condition. From the accumulated dust it was evident that they had not been used recently for teaching purposes. At Des Moines on shelves at one end of a room designated Physiology Laboratory there were seven or eight bottles containing fetuses of various ages. This was the only collection. At Philadelphia were four or five dozen bottles bearing specimens, chiefly gynecologic or obstetric."

Of the dearth of postmortems there was abundant evidence. At Kirksville the practical course in pathology consisted of a study of microscopic sections, some prepared locally, others purchased. To a question regarding autopsies, the dean made reply "You know how opposed to postmortems are people in a country district. We probably have ten a year but in any case they are pitifully few. At Des Moines they laid claim to one a year, this being done at an undertaker's establishment."

Enough has been said on this point to prove beyond peradventure that the study of pathology is conspicuous by its absence, more honored in the breach than the observance. Comparison with the course given in our medical schools cannot be made all is contrast. Any one who holds otherwise either does not understand what is involved or seeks to convey a false impression.

CLINICAL TEACHING

What clinical training is given to the thousand or two young men and women in these schools endeavoring to qualify to treat disease? To answer this permit me to transcribe a note made at the Kirksville school. Let us examine conditions as seen at the first-formed and now the largest osteopathic center which boasts of an attendance of 627 students of whom fifty-eight are women. At the outset this fact must be emphasized for it can-

not be given too great prominence. Kirksville is an isolated country town whose population is said to be about 8,000. That is to say, there is here an enrolment about equal in number to the attendance at Toronto. To any one who has an appreciation of the magnitude of the task of providing adequate laboratory and hospital facilities needed for 600 students there would come an immediate thought that under the most favorable conditions (such as large endowments association with a strong university, organization along the lines of the one at Iowa City) which do not exist, the thing could not be done at Kirksville. And I say, without hesitation, it is not done, it is not even seriously attempted.

"The building devoted to hospital service is old, dirty and in a state of disrepair. Whole areas of plaster fallen from the ceiling had not been replaced. With a total bed capacity given as fifty-five, we estimated the number of patients at fifteen. On the first floor was an antiquated amphitheater seating about 100. The seats and facings were of tongue-and-groove lumber the paint chipped and stained. Here, we were informed, students observed women in labor. Modern midwifery could have no place in these surroundings, and this plan of attempting to teach obstetrics must, we think, represent the absolute minimum—and less. It is scarcely necessary to say that the hospital arrangements were grossly even lamentably, inadequate. The step between this inadequacy and total absence is indeed short.

(An adjacent private hospital was not used for teaching purposes and is therefore not here considered.)"

At Des Moines "From the school building originally an insurance office, we were driven some three miles across the city to visit the hospital affording clinical facilities for the students. We found a converted private house with a capacity of thirty-five, averaging twenty patients. Students had the privilege of visiting this institution on Saturdays. Comment is withheld because none is needed."

The inevitable conclusion from these facts is that not only is competent clinical training not given, it is not seriously undertaken.

In the place and stead of clinical training by which I mean bedside observation on the nature and course of disease its examination and recognition, its treatment and cure, there is substituted in these schools an extensive course in osteopathic manipulations. Conspicuous in each of them is a section containing a number of bare cubicles furnished with only a couch, where the distinguishing rites and ceremonies of the cult are performed. To this undiscovered country, from whose bourn we were duly to return, we now directed our eager steps. At last the great mystery was to be solved, the veil torn from the sacred altar and the holy ceremonial exposed to mundane and heretical eyes. But I am obliged to dash your hopes raised so high, by telling you in simple language what we saw.

1 In the first of the thirty-seven cubicles was a girl in her teens. She complained of pain in the neck. A student was holding her head in his hands and aimlessly moving it about in various directions.

2 In the second were two students, one being the patient. Complaint pain in the back. He lay prone on the couch while his fellow pushed and shoved his shoulders and back.

3 Next a man of 50 said he had been attending this clinic for eight years. Suffering from syphilis and locomotor ataxia he had received arsenic and bismuth. As he lay on his belly a student was elevating his legs and hyperextending his back.

4 An adipose middle-aged woman lay on her back. Complaint painful feet. She was fully clothed except that her shoes had been removed showing flat feet and bunions. Her toes and feet were being bent in all directions.

5 A woman of 25 lay face down fully clothed. Recorded diagnosis bilateral brachial neuritis. Her history read pain

and stiffness in the shoulders, along the base of the neck and in the arms, also headaches." Manipulation of the dorsal and lumbosacral regions, described as relaxation and correction treatment, was being done.

In the couple of hours spent in this clinic, we saw nothing more informing than these reported cases. Neither nurses nor instructors were present. No patient had the clothes removed for examination. An occasional patient was sent on to another department, as eye and ear. When our guide, in charge of the clinic, was asked the meaning of certain signs and abbreviations on the osteogram charts, he was unable to recall their meaning but presently found a senior student who supplied the information.

In the Chicago school a student is required to give a minimum of 600 osteopathic treatments. In the Philadelphia clinic 14,601 patients were treated in six months, 11,293 of whom had paid the full fee of \$2.

The impression carried away was that this department of manipulation, termed the General Clinic, formed by far the most important part of the setup. Whatever a school might lack in equipment, in hospital facilities and all that goes with them, however superficial the consideration given to the fundamental sciences, however gross the absence of a scientific point of view, there were always present rows of cubicles with their couches in which patients had their several parts pushed and drawn about in all directions. In this connection I may express my disappointment and surprise in failing to observe manipulations worthy to be described as skilful, dexterous and purposeful.

COMMENT

But I may now be asked "What has all this to do with the question of licensure?" The connection is clear, the answer not far to seek. Over a long period of years there has been evolved in every civilized country a standard of preliminary and professional education which in the interest of the people is justly required of those who are to be entrusted with the heavy responsibility of caring for life and limb, of guarding the public health, of the protection of women in labor and of the prevention and cure of disease. From time to time there press forward blatant, self-seeking groups, demanding in the name of the law rights and privileges to which their knowledge and training do not give them title. Any thoughtful man must shudder to envisage the result to women in childbirth if their care should be placed in the hands of those who do not believe in, and have not been thoroughly trained in, the bacterial cause of infection. And what dire calamities would immediately and inevitably befall our great centers of population, if their supplies of food and water and their sewerage systems should be controlled not by men who have devoted long and arduous years to the medical sciences but by those uninstructed and misinformed individuals who believe disease (e. g., typhoid and diphtheria) to result from the pressure of bony irregularities on nerve?

Such, I submit, are reasonable questions and demand frank answers from politicians who would barter the people's health for the votes of a clamorous minority. If the osteopath protests on the ground that I am misrepresenting him and that he also 'accepts the proved theories of present-day bacteriology and uses Zinsser's textbook' I reply: 'You are neither an osteopath nor a regular but for your own purposes practice a hypocritical and bastard system. You are beyond the pale and deserve no consideration.' Or as one of their own authorities writes, "These modern skeptics, these doubters of the truth of Still's back-bone theory of disease live and grow prosperous on that theory while they doubt the truth of it in their hearts."

Let there be in the interest of the nation a common standard of training and examination for all aspirants to the practice of the healing art. Let there be one avenue of approach, one portal of entry.

Medicolegal

Malpractice Liability of County Hospital—The defendant hospital was organized pursuant to chapter 169, Statutes of Nevada, 1929, which provided that any county in the state might establish a public hospital. The plaintiff, a pay patient, entered the hospital for care and treatment. As the result of the negligence of the hospital's nurse, it was alleged, a liquid not prescribed by the plaintiff's physician was instilled in her eye, destroying the sight of the right eye. The trial court dismissed the action brought by the plaintiff to recover damages from the hospital and she appealed to the Supreme Court of Nevada.

It is a well recognized general rule, said the Supreme Court, that a county cannot be sued without legislative consent. Conceding the correctness of this general rule, the plaintiff contended that it did not apply in the present case. The establishment of the defendant hospital, it was argued, was not mandatory, and since the acceptance of the plaintiff as a patient was discretionary, and no governmental function was involved in her treatment and care, the same rule of law should apply to the defendant hospital as would apply to an individual or corporation operating a hospital for profit. Furthermore, it was argued, the county had nothing to do with the management and control of the institution, the management and control being vested in an agency created by the legislative enactment. The liability of an organization created by or organized pursuant to statute, said the court, is dependent on the intention of the legislature in enacting the law. The act under which the defendant hospital was organized provided that "any county may establish a public hospital in the following manner." The act did not create a corporation but merely authorized the respective counties to establish a hospital, and it did not provide that such hospital might sue or be sued. All moneys raised by taxation pursuant to the act for the establishment of county hospitals are collected as other taxes are collected and must be credited to the 'hospital fund.' The money so collected "shall be paid out on the order of the hospital trustees for the purposes authorized by this act, and for no other purpose whatever." The title to all property donated for the benefit of such a hospital is vested in the county. It seems to us, said the court, that the legislative intent is plain to create a public institution which should own no property, have no income and no method of raising money and hence no ability to pay anything. Certainly it was not the legislative intent to make such an institution liable in damages for any act done in carrying out the purposes sought to be obtained. Furthermore, the court said, the failure of the legislature to provide that the defendant might sue and be sued was a conclusive reason why the present action could not be maintained. The judgment of the trial court was affirmed.—*McKay v. Washoe General Hospital (Nev.)*, 33 P. (2d) 735.

Evidence Credibility of Expert Witnesses—The Prudential Insurance Company of America issued to the deceased a life insurance policy in which was incorporated an accidental death benefit clause. On the death of the deceased, the plaintiff as beneficiary under the policy sued for the accidental death benefit and obtained a judgment in the trial court. The insurance company appealed to the Supreme Court of New Hampshire.

Prior to the accident, the deceased had enjoyed good health and had never suffered from any pain in the region of his heart or from any abnormal shortness of breath. While engaged one afternoon in operating a circular splitting saw, the deceased was struck on the right forearm by a small piece of wood, weighing only a few ounces, which was thrown back by the saw. A V-shaped wound, approximately an inch and three quarters on each side, and about an eighth to a quarter of an inch deep, was inflicted. A physician cleaned the wound and closed it with seven stitches. At the doctor's office, on the way home, and during the early evening, the insured was pale or, as some witnesses described it, was greenish in color, had difficulty in breathing, and complained of intermittent pains in the region of his heart. Later in the evening he died suddenly. A physician who performed the autopsy on the body testified that

he found the heart in a condition to indicate that the insured was suffering from and had died of angina pectoris. Other medical experts, called by the defendant, testified to the same effect in answer to hypothetical questions. Two physicians who testified for the plaintiff, in answer to hypothetical questions, stated that the insured died of an embolism which formed at the wound on the forearm, proceeded in the blood stream to the heart, and lodged in the pulmonary artery. The defendant contended, among other things, that the jury in finding a verdict for the plaintiff erred because the testimony of the plaintiff's expert witnesses was clearly incredible.

To support this contention, the defendant argued that the witnesses had never seen a case of pulmonary embolism, verified by autopsy, resulting from a superficial, uninfected wound of the forearm, and that they disagreed with a statement found in a textbook on surgery published in 1917 to the effect that infection is an essential prerequisite of embolism from wounds. Both witnesses, said the court, were men of long practical experience as practicing physicians and surgeons. Both testified that they had seen cases of pulmonary embolism result from superficial uninfected wounds. The fact that the witnesses had never encountered, and verified by autopsy, a case of pulmonary embolism which had resulted from a precisely similar wound as the one in this case at most affected their credibility. Their disagreement with the statement read from the textbook, and their willingness to follow their own experience even if that ran counter to statements to be found in all texts, likewise affected only their credibility. The witnesses were practical as well as theoretical experts. If their practical experience was at variance with the authorities, they could either follow what their experience taught them or else conclude that their observations were wrong and follow the authorities. In the instant case, they elected to follow their own experience. Their abandonment of authority may, of course, be shown to affect their credibility, but not to such an extent as to render their testimony valueless. We are not prepared to hold, concluded the court that, as a matter of law, the testimony of an iconoclast is always without probative force. The verdict for the plaintiff was upheld and judgment was rendered on the verdict.—*Ricard v Prudential Ins Co of America (N H)*, 173 A 375

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Bronchiogenic Cancer Combined with Tuberculosis of Lungs—Fried reports thirteen cases in men in whom both tuberculosis and cancer were present in the same lung. The tuberculous lesion found in the lungs of the patients was of the healing fibrotic type being to all appearances of long standing. Most of the patients had had a history of cough extending over a number of years. In two cases there probably occurred a recent dissemination of the bacillary infection (causing a slight exacerbation) in which the advancing cancer may have played a biologic (lowering of resistance) and a mechanical part. The malignant condition had then developed independently from the tuberculous disease in some cases, while in others it was engrafted on an ancient fibrotic infection. In five of the thirteen cases a correct diagnosis was made in other institutions but had not been suspected by the private physicians who attended the patients for some time prior to hospitalization. Eight of the patients were admitted to the hospital with no diagnosis or with one of tuberculosis of the lungs. From the histories present it is seen that the patients had been ill for a considerable length of time and that their symptoms and physical signs were suggestive of malignant disease of the lung. They entered the hospital when the disease was advanced. In three patients there occurred a spontaneous pneumothorax on the side affected by the malignant disease. The author stresses the point that in any case of chronic pulmonary disease in a person of middle or past middle age with persistence of symptoms, particularly if it is accompanied by a progressive loss of weight and strength the possibility of malignant disease should always be considered also that the presence of pulmonary tuberculosis does not exclude the existence of a malignant process in the same lung.

Myxosarcomas—Thibadeau and Kress studied fifty-one cases of myxomatous tumors including forty-two myxosarcomas and nine myxofibromas. Three cases of lipomyxosarcomas are included with the myxosarcomas as they differed from them in

no respect in their clinical course and in their response to treatment. The occurrence of myxomatous tissue in a tumor is not an evidence of degeneration. Myxomatous tissue is a derivative of connective tissue and can probably originate from the metaplasia of different types of connective tissue. The more malignant a myxomatous tumor, the more cellular it becomes. Myxosarcoma is clinically a highly malignant tumor, responding only occasionally to recognized forms of therapy. As a group the myxosarcomas are resistant to radiation therapy; some tumors, however, have responded admirably to this type of treatment. Myxosarcoma is most apt to arise between the ages of 40 and 60 years, it shows no special predilection for either sex. The shorter the clinical duration of the tumor before treatment, the more satisfactory is the response to therapy. Cases of myxosarcoma in which recurrences have occurred do not respond to treatment. Widely disseminated metastasis occurs late in myxosarcoma. Myxofibroma is readily eradicated by surgical treatment only, surgery and roentgen radiation, or roentgen radiation alone.

Blood Glutathione in Human Cancer—Schoonover found the average glutathione contents of the blood in untreated and treated cancer cases and in nonmalignant conditions to be practically identical with those of normal subjects. In the cases showing liver damage the contents were somewhat lower. Moreover, the ranges of the results from which these averages were drawn show fairly close agreement. The slightly increased red cell glutathione content of cancer blood is not significant in view of the decreased erythrocyte count, and especially in view of a similar increase in the blood in the nonmalignant cases in which the erythrocyte count is likewise low. Since the blood cells contain nearly all the reduced glutathione, low figures are to be expected in anemic conditions. While the cases in the author's series present a lowered average erythrocyte count, an advanced stage of anemia, with a count lower than three millions, was seen in but three. It is therefore possible that the low whole blood figures reported by Uihari and by Truhaut and Minopoulos were the result of a greater degree of anemia in their patients. In view of the fact that the erythrocyte glutathione appears to be slightly elevated in nonmalignant conditions, it seems justifiable to indicate that comparisons of malignant and nonmalignant cases should not be used as evidence that cancer lowers the blood glutathione concentration below the normal level.

Diverticula of Upper End of Stomach—Cunha alleges that more careful scrutiny of the upper end of the stomach and particularly of the cardio-esophageal junction during fluoroscopy

scopic examination would show that the instances of diverticula in this area are more common than supposed. He has seen fifteen such cases during a period of two years. The finding of these diverticula would help to explain the symptomatology in many cases in which the observations are said to be negative. There is association of a considerable number of these cases with ulcer and pylorospasm. The possibility of obtaining a past history of prolonged period of abnormally increased intragastric pressure, such as was obtained in the author's two cases of pertussis, and in women a history of a prolonged period of pernicious vomiting of pregnancy should not be overlooked. Treatment should be medical rather than surgical, owing to obvious technical operative difficulties. The differential diagnosis of true diverticulum is not difficult, penetrating ulcers having different outline characteristics as illustrated in two cases. The possibility of ulcer within the lesion itself must be kept in mind. The occurrence of carcinoma in one of these diverticula, although extremely improbable if based on past post-mortem experience, should be kept in mind because of the irritative factors present.

Surgery of the Diabetic—Leonard urges a standardized hospital routine for the care of diabetic patients subjected to surgery with the responsibility vested solely in the surgeon until the surgical period is over. Every patient having diabetes who is operated on should be regarded as a candidate for coma, and its prevention is better than the cure. A high carbohydrate intake for a period of one week before operation should be the rule unless a surgical emergency arises. The carbohydrate intake varies with the individual patient, but, in the author's opinion, should never be less than 150 Gm. in twenty-four hours and, if the patient is obese, should be as high as 225 Gm. Insulin is used in any amount necessary to control any glycosuria that may arise. When the patient returns from the operating room he should receive approximately the same amount of insulin in twenty-four hours that he was receiving on his regular diet. Dextrose should be given in amounts equal to his sugar producing intake on his regular diet. Insulin should be given in small repeated doses so that at least 75 Gm. of dextrose is metabolized every twenty-four hours in the average patient, in the obese, 150 Gm. of dextrose should be metabolized. All urine should be tested for the presence of sugar and diacetic acid. The plasma carbon dioxide combining power is estimated whenever there is any clinical evidence of acidosis. If the acidosis is under control and symptoms of alkalosis occur (prostration and tetany), a close check should be kept of the carbon dioxide capacity of the blood. The slightest acidosis or alkalosis must be combated vigorously. The healing of operative wounds is somewhat delayed, owing to the peculiar lack of resistance to skin infections even in well controlled cases of diabetes. The healing of chronic ulcers or indolent wounds requires the closest application of surgical technique and control of sugar metabolism. Most patients with diabetes particularly those requiring surgical procedures, are advanced in years, overweight and suffering from circulatory disturbances and other degenerative lesions, which of themselves make the surgical risk serious.

Congenital Defects of Lumbosacral Joints with Associated Nerve Symptoms—Wagner stresses the point that one must, as a rule, learn the exact anatomic structure and the lesion of the congenital variations of the lumbosacral joint if an accurate diagnosis is to be made and the proper treatment applied. Neurologic study is always indicated to exclude spinal cord tumor or radiculitis. Congenital lesions of the lumbosacral joint may be of a diversified nature but are more subject to strain than the normal vertebral articulations. The possessors of such variations are usually the persons who go through life suffering from chronic undetermined backache often with little disability. The defective articular facet is most of all to be associated with defects in the pedicle and laminae of the vertebrae. This type of case sooner or later presents neurologic symptoms and signs. In an analysis of twelve cases of congenital defects of the lumbosacral joint all of which have been studied and proved the occurrence of pain was as follows: pain in the sacro-iliac region ten cases; pain in the vicinity of the lumbar muscle of the affected side twelve; bilateral one, pain over the sacrolumbar joint, ten; pain on the opposite side, one; pain in the gluteal muscle and hip four; pain on the outer side of the thigh and knee five; pain along the sciatic

nerve, three; numbness about the outer side of the leg and calf, four; and pain about the instep, five. Pain could be produced by certain movements. In lumbosacral anomalies the subjective pain is segmental in distribution, being completely localized to the areas supplied by the first, second and third segments. The inflammation about the spinal column and its articulations causes spasm of the lumbar muscles with a physico-chemical irritation of them and a great deal of the pull on their periosteal attachments with a further demonstrable tenderness. The rotation of the fifth lumbar vertebra associated with a too adherent dura to the spinal nerves as they make their exit from the vertebral foramina or the narrowing of the intervertebral foramina must transmit such irritability to the spinal cord of the nerves supplying the muscles, ligaments and periosteum affected.

Significance of Systolic Murmur—Friedlander and Brown observed the effect of amyl nitrite in the production of murmurs in 100 persons showing no evidence of heart disease. A systolic murmur developed in forty-seven. In none did a diastolic murmur or a systolic murmur of grade 3 or greater occur. Murmurs of grade 1 were about twice as common as those of grade 2 and they were more common at the pulmonary region than at the apex. The systolic murmur that develops following the use of amyl nitrite was found not to be due to the increased pulse rate but to be present as the rate began to slow. Twenty-six observations in twenty patients were made on the effect of fever. In only four were systolic murmurs detected. Observations in a small group of cases with anemia indicate that the relationship between anemia and the development of the systolic murmur is inconstant. There are some cases, however, in which the presence of the former, of itself, can account for the latter. In the production of systolic murmurs a factor of some importance is the velocity with which the blood is ejected from the heart. In many of the conditions (apart from organic heart disease) in which systolic murmurs are present, the velocity of the blood flow is increased. The fact that systolic murmurs of grade 3 or greater were not detected in the conditions that were investigated is further evidence that these louder murmurs are probably associated with organic cardiovascular disease.

Dual Nature of Action of Insulin on Heart—Soskin and his associates studied the effects of adequate doses of carbohydrate in animals that had received large doses of insulin. The carbohydrate was administered either before or after hypoglycemia had occurred. The results of these experiments made it desirable to study animals in which hypoglycemia was produced without hyperinsulinemia. For this purpose exsacration was employed. In the exsacration experiments, changes in the electrocardiograms accompanying hypoglycemia were observed that were reversible on the administration of dextrose. Hypoglycemia caused a decrease in the amplitude of the upright T wave in all leads. In two cases the upright T wave actually became inverted during hypoglycemia. In one animal the control electrocardiographic records after operation showed inversion of the QRS complex in leads II and III. Hypoglycemia in this case increased the amplitude of the upright T wave in these leads. These changes persisted and progressed with the

hypoglycemia, and the changes in the T wave disappeared only on the elevation of the blood sugar level by the administration of sugar. The magnitude of the changes due to hypoglycemia could not be strictly related to the degree of hypoglycemia that occurred. With two exceptions, no change was seen until the blood sugar fell below 30 mg per hundred cubic centimeters. In addition, progressive changes were observed in the electrocardiogram which bore no relationship to the glycemic level. Characteristic electrocardiographic changes, unrelated to the glycemia level, also appeared when the blood pressure fell to extremely low levels. In such instances, an increase in blood pressure brought about by the injection of isotonic sodium chloride solution returned the electrocardiogram toward normal. However, sodium chloride solution repeatedly failed to affect the electrocardiographic changes accompanying hypoglycemia which were reversed by the injection of sugar. These results demonstrate beyond doubt that hypoglycemia affects the electrocardiogram.

Erythema After Administration of Arsphenamine —

Keim believes that the essential features of erythema of the ninth day following the administration of arsphenamine are sufficiently characteristic to distinguish the syndrome from the ill defined group of so called mild reactions to arsphenamine. Evidence is presented showing that the recognition of this typical mild reaction will in most cases make possible the differentiation of this mild, self-limited medicamentous dermatitis from the serious vesiculo-edematous erythrodermia which leads to crustaceous dermatitis and exfoliation. A possible explanation of the mechanism of production of erythema of the ninth day is suggested by the theory that the arsenical radical of the drug may not be responsible for the self-limited train of symptoms, which distinguishes erythema of the ninth day from true arsenical intoxications. The phenol content of the molecule may possibly explain this type of dermatitis, a hypothesis supported by Weiss's experimental evidence of the retention and elimination by the dog of free and conjugated phenols after a single maximal tolerated dose of neoarsphenamine. Further treatment with arsphenamine after erythema of the ninth day is considered not to be warranted by the facts at hand. Additional treatment for a patient with early syphilis is justified if the accident has been properly interpreted as

uncomplicated erythema of the ninth day. The author questions the value of the administration of sodium thiosulphate and other detoxicating measures in the treatment of this self limited intoxication. Four of his ten patients received no sodium or calcium thiosulphate, and there was no alteration in the self limited signs or symptoms. The disease in other patients from whom the treatment has been withheld has likewise followed the same limited course as in the treated patients.

Effect of Hormones of Sex Glands on Acne—Van Studdiford gave female patients of various ages between the periods of adolescence and the menopause 10 grains (0.65 Gm.) of a desiccated extract of the whole ovary daily. The treatment was begun five days after the cessation of menstruation and continued until the next period. Fractional doses of roentgen radiation were given at weekly intervals. Of the 284 acne patients thus treated 130 showed no improvement within eight weeks. Of these, six suffered from infections of the sinuses, ten from latent infections of the teeth and two from intestinal ova. Two gave positive reactions to tuberculin, two were unable to continue the use of the ovarian extract because of the appearance of sexual stimulation and nervousness and two used iodized salt. In seventy-six of the patients, improvement began within six weeks. Of these, one lost 30 pounds (13.6 kg.), three received combined ovarian and orchic extracts, three, whose periods had been markedly irregular, menstruated regularly and four used iodized salt. In thirty-five of the patients, improvement appeared within five weeks or less. Of these normal menstruation was restored in three, pregnancy proceeded to term in three and five used iodized salt. Because of the frequently observed curative effect of marriage on women with acne 15 grains (1 Gm.) of orchic extract was given daily to twenty-seven women, with the following results. Of eighteen patients who had previously been given ovarian extract over a long period, ten failed to show improvement and eight improved, one of whom was relieved of the accompanying nervous symptoms. Of nine patients who were given orchic extract alone two failed to improve and seven showed improvement. Of the fifteen patients who received three doses of estrogenic substance of 50 rat units each on alternate days beginning seven days before the calculated menstrual period eleven improved. Of these, six menstruated normally within three months, two after amenorrhea of a duration of five years, two after periods of irregular menstruation since adolescence and one who had undergone oophorectomy one year previously menstruated and showed improvement. Of sixteen amenorrheic patients who were given the daily injection of 50 rat units (folliculin or antuitrin S) during a period of five or six days just after the time for the cessation of menstruation as calculated and 50 rat units of estrogenic substance every other day for three doses, commencing seven days before the next menstrual period, eight showed improvement and menstruated regularly. Of the others, four showed improvement but menstruation was still irregular, occurring at intervals of from thirty-five to forty days and four remained without improvement. Orchic extract 15 grains (1 Gm.) daily, was administered by mouth to nine young male patients with no improvement in the symptoms of acne. However, as certain hemophilic males are said to have reacted favorably to the administration of ovarian extract, three doses of 5 grains (0.3 Gm.) of the desiccated ovarian extract were given by mouth to ten boys. Five showed improvement before receiving four doses of roentgen rays and five showed no improvement.

White Sponge Nevus of Mucosa—Cannon on examining a woman for a banal skin eruption found a peculiar whitish lesion of the mucous membrane of the mouth. Further investigation revealed a similar discoloration of the mucous membrane of the labia, the vaginal walls and the upper part of the anal canal and the rectum. One of the patient's two children aged 13, the patient's mother, a brother, two sisters and a maternal aunt had the same "white mouth." The possibility of the development of a malignant process caused considerable anxiety, as there was a familial history of cancer. A specimen of tissue from the mouth was taken for biopsy. This patient and three members of the family, representing three generations, were healthy and showed no other abnormalities. There was no history of consanguinity among the forebears and no other congenital abnormalities could be ascertained. The maternal

grandfather of the patient and one sister of the patient's mother died of cancer, but there seems to be no ground for considering the present condition as even potentially cancerous unless some change occurs subsequently in the affected areas in one or more of the members still living. The patient's experiment with smoking is interesting by virtue of its analogy to the part smoking plays in the evolution and malignant degeneration of some types of leukoplakia of the tongue. In this instance not the slightest change could be detected after a period of two years during which the patient smoked as many as twenty cigarettes a day. The complete absence of any subjective disturbances and of any signs of inflammation in the parts involved, the static nature of the process and its strict limitation to the buccal rectal and vaginal mucosa and that of the upper portion of the anal canal, coupled with its congenital, hereditary and familial basis (three generations on the maternal side) suggest its classification among the nevi. In the absence of a heretofore recorded parallel, the author proposes the name "white sponge nevus of the mucosa" (*nævus spongiosus albus mucosae*).

Dysphonia Plicae Ventricularis—The Jacksons state that phonation with the ventricular bands is a rather frequent and usually unrecognized cause of hoarseness. It may be a vicarious dysfunction with a pathologic basis or a physiologic compensation for lost or impaired vocal cords. When it is a desirable compensatory function, a good voice can be developed by systematic training. When it is a usurpation of function by aggressively overactive ventricular bands or when the resumption of activity by temporarily disabled vocal cords renders persistent phonation with the ventricular bands undesirable, this phonation can be checked by training or, if necessary, by operation. The operation consists in nipping out a bit of tissue from the middle of the free edge of one or both ventricular bands. Before this is done, however, it is necessary to be certain that the vocal cords can approximate, draw tense and vibrate.

Agglutinins for Sheep and Rabbit Erythrocytes in Human Serums—Stuart and his collaborators observed that in individual serums normal with respect to horse serum sickness and infectious mononucleosis, there is quantitative relationship between the two agglutinins. Although their results indicate that such a relationship does exist, it is not a hard and fast rule. In the 760 serums examined, titers above or below normal in one agglutinin in any one serum indicated for the most part correspondingly high or low titers for the other agglutinin. The relation of warm to cold (37 and 5 C) agglutinin titers in normal serums is puzzling. It would appear that the warm titer could increase or decrease markedly without a similar quantitative fluctuation in the cold titer. This does not necessarily mean that the warm and cold sheep agglutinins in human serums are two separate agglutinins for sheep erythrocytes. The ratio average cold/warm rabbit titers is not too large to be explained by a difference in adsorption and dissociation between the cells and the agglutinins at the high and low temperatures. Work now in progress tends to confirm this assumption. The statistically significant sex difference was found in both sheep and rabbit agglutinin titers in human serums, with the higher agglutinin content in female serums.

Diphtheria Immunization with Single Injection—Lerch and his associates selected 728 children from 2 to 11 years of age, of whom 553 were injected with a highly purified formol toxoid, with 10 per cent by volume of aluminum hydroxide, leaving 175 as controls. The toxoid was administered in 2 cc doses injected subcutaneously at the inferior angle of the left scapula. Of the 553 children receiving a single injection, seventy-one showed local or general reactions. These reactions are generally supposed to result from a hypersensitiveness to the specific diphtheria antigen. The reactions in the group of children who had had diphtheria were twice as frequent as in the group with no history of diphtheria. The reactions were not alarming in character. There were no abscess formations. The antitoxin content of the serum was determined in blood samples taken immediately before and twenty-eight days after the injection of antigen. The antitoxin determinations were made by the intracutaneous rabbit method of Jensen. Every sample of blood was accurately titrated by two or three successive determinations of increasing exactitude. In this manner each titration served as a control for the preceding titration on the same serum and any chance of error was thus avoided. The method makes possible the detection of traces of antitoxin as low as 0.00005 unit per cubic centimeter of serum. An increase in antitoxin titer was found, and in the majority of cases this increase was considerable. No evidence of a negative phase was found. No cases of diphtheria occurred among the immunized children after the immunization. During the five months following the administration of the antigen, seven cases of diphtheria occurred among the group of unimmunized children.

Immunotransfusions in Treatment of Acute Infections—Crocker and his co-workers employed hemography-controlled nonspecific immunotransfusions in fifty-two cases of acute general infections, including pneumococcal and streptococcal pneumonia, postoperative septicemia and peritonitis, hemolytic streptococcal septicemia, and puerperal and postabortive sepsis. The elimination of the primary focus of infection or the establishment of adequate drainage is of equal importance in all cases. Of the fifty-two patients, twenty-five recovered and twenty-seven died. The same general clinical types of disease

appear in each group (the recovered and the fatal). Of the first group, blood culture was positive in five cases of *Streptococcus haemolyticus*, one of *Staphylococcus albus* and one of pneumococcus type I. In the second group, blood culture was positive in four cases of *Streptococcus haemolyticus*, five of *Staphylococcus albus*, one of *Staphylococcus aureus* and three of pneumococcus type IV. The hemogramic prognosis was equally bad in all cases before nonspecific immunotransfusion was begun. From twenty-four to forty-eight hours after the last treatment the hemogramic prognosis was good in the twenty-five patients who lived. In the fatal cases the hemogramic prognosis from twenty-four to forty-eight hours after the last transfusion was generally bad. In estimating the value of nonspecific immunotransfusion therapy, the authors believe that it is only fair to point out that of the twenty-seven patients who died six were incurable, fourteen had complications with other serious conditions and in the remaining seven there were either no complications or no necropsy was performed. The average number of days of illness that elapsed before treatment was seventeen in those recovering and twenty-three in those dying. Many of the patients who failed to recover were in apparent need of more than one transfusion but additional donors were not to be had. This may have reduced the possibility of success with this form of therapy. Nonspecific immunotransfusion should be used as early as possible in all severe septic conditions. It seems to abort pneumonia. It is not contraindicated in the late stages of disease.

Heterophile Antibody Reaction in Diagnosis of Infectious Mononucleosis—Butt and Foord offer corroboratory evidence, having performed the test in eighteen cases of infectious mononucleosis and tested the serums of 412 hospitalized adult patients for sheep cell agglutinins, in support of Paul and Bunnell's test for infectious mononucleosis. The points of interest are that the presence of heterophile antibodies in high concentration is a constant feature of the disease, that the production of heterophile agglutinins is roughly parallel to the leukocytosis and that the height of the agglutinin response is dependent on the stage of the disease in which the serum is obtained for testing. A nonspecific fixation of complement was not obtained in the Wassermann test with serums containing high concentrations of heterophile antibodies.

Intravenous Administration of Fat—Holt and his co-workers used emulsions for purposes of parenteral feeding in sixteen infants with severe nutritional disorders, who received from two to seven injections each on successive days, the dose was 1 Gm of lipid per kilogram of weight in all but a few instances, in which twice that quantity was given. A number of these cases were hopeless from the start, the patients being infants with tuberculous or pyogenic meningitis, peritonitis or septicemia, the fatal outcome that ensued can hardly be held against the treatment. In other instances, even though recovery took place it cannot be credited to the treatment, for other therapeutic measures—fluids, transfusions—were given simul-

taneously. The authors present three cases, however, in which they gained the impression that the treatment had been responsible for improvement.

Acute Interstitial Pneumonia—Solis Cohen describes a rare form of acute interstitial pneumonia that was discovered at necropsy in six infants and two children. The most characteristic feature is the histologic appearance of the affected portions of the lung, which present capillary engorgement and infiltration of round cells, epithelioid or plasma or endothelial cells and in some cases polymorphonuclear cells, which is not abscess formation. Other characteristic features are the muscle-like feel of the affected portion of the lung and its peculiar color. The cases presented no characteristic clinical, roentgenologic or laboratory changes by which they could be recognized during life. The most prominent clinical features are the commonly short duration of the disease, the virulence of the infection, its fatality and its failure to respond to treatment. Leichtenstern, Buhl, Stokes Corrigan, Gordon and Gouley and Eiman are the only ones found by the author to describe conditions closely resembling this form of acute interstitial pneumonia.

Lesions Resembling Pneumonia as Result of Allergic Shock—Waldbott and Snell assert that in allergic patients pulmonary infections resembling bronchopneumonia may arise as the result of allergic shock and of severe asthma. They present evidence suggesting that these lesions are superimposed on an edematous hemorrhagic process of allergic origin in the lungs. In seven of twelve asthmatic children who had been hospitalized for pneumonia the infectious process may have thus been originated. In an attempt to differentiate this type of pneumonia from other pulmonary lesions, the following clinical features were found to be of diagnostic value: the presence of an afebrile period with collapse and associated asthmatic symptoms, a lesser severity of the infection and a shorter duration than in ordinary pneumonia, and a relatively low white blood count at the onset of the febrile period.

Quinine Bismuth Iodide in Treatment of Syphilis—Oliver and Crawford selected a series of seventy-six uncomplicated cases of syphilis without regard to the stage of the disease. No parietic tabetic or cardiovascular cases or any with involvement of the central nervous system were included. No obviously serofast cases were selected. All had a general checkup including a serodiagnosis and urine before a course of fifteen injections of quinine bismuth iodide was begun. The patients were questioned as to pain following injections, itching

skin eruptions, jaundice, stomatitis, urinary symptoms or gastro-intestinal disturbances, any of which might not have been picked up in the routine interview each week. At the same time a similar series of cases was selected from the larger group of patients in the clinic as a whole who were getting bismuth salicylate. The same restrictions were exactly adhered to throughout and the same type of case picked for each one receiving quinine bismuth iodide, i. e., according to the stage, the status of previous treatment and the condition of the patient. In addition to the present series of cases another group of 118 patients who had received both types of bismuth salt in the past and are still under observation was studied from the subjective angle. Their interrogation was facilitated by the variance in color of the products. The results as tabulated suggest that quinine bismuth iodide, in spite of its lower bismuth content, is superior to bismuth salicylate. The additional series of cases was found to substantiate the results obtained in the present series, in that quinine bismuth iodide produced a markedly smaller number of unfortunate incidents.

*Administration of Oxygen by Intranasal Catheter L E Barron and G M Curtis Columbus —p 196
Asthma Due to Bacteria Atopic Type J Forman Columbus —p 200

Unusual Complications in Malarial Therapy—Karnosh and Williams made a survey of 580 cases of dementia paralytica that were subjected to the paroxysms of tertian malaria. Prime evidences of serious complications were found to be a paroxysm with a temperature of 41 C (105.8 F) or more, a low chill temperature accompanying an unusually high pulse

and respiratory rate, a fever that remained for more than eight hours after a normal chill peak, a blood pressure under 100 systolic and 60 diastolic, a blood urea of more than 60 mg., and cyanosis of any degree. Delirium, confusion and excitement during the height of the fever occurred in more than 75 per cent of the cases and cannot in themselves be regarded as having significance. The same can be said of herpes of the lips and face. Physical habitus offered no reliable index as to resistance. Roentgen diagnosis of dilatation of the aortic arch, unless it was associated with pronounced clinical symptoms, did not contribute to a greater number of fatalities than did a negative observation. Fatalities from all causes occurred in seventy-four, or 127 per cent. Bronchopneumonia was found in 35 per cent. The unsatisfactory diagnosis of circulatory failure in thirty-two cases could not be clarified, because no postmortem examination was allowed. Hemorrhages, hematomas and noninflammatory ulcers of the intestine may be said to be specific lesions due to malarial infection. Enlargement of the spleen is also a characteristic sign, and rupture of this organ may occur and result in immediate shock and death. No specific lesion of malaria can be demonstrated in the brain tissues from a study of the material in twenty-three cases. Rapidly fulminating septic states may apparently develop in otherwise normally resistant patients after malaria is injected, suggesting a symbiotic relationship between the plasmodium and many pathogenic organisms.

Administration of Oxygen by Intranasal Catheter — Barron and Curtis claim no originality in describing the administration of oxygen by the intranasal catheter but emphasize its simplicity, efficiency and economy. The method described by Barach has in their experience produced highly satisfactory results. Its simplicity makes it available for use in the office, in the hospital and even in the home. Six cases are cited which illustrate the clinical occurrence of anoxemia, in the management of which oxygen, by the intranasal catheter was used successfully.

The Esophagus in Relation to the Heart and Aorta—Brown and McCarthy observed that the following abnormal conditions affected the position of the esophagus to a more or less degree: thoracic deformities, pleuropulmonary disorders, lesions of the mitral valve, lesions of the aortic valve, general enlargement of the heart with or without aortic dilatation, congenital heart disease, dilatation of the aorta with or without aneurysms, and pericarditis with or without effusions. Enlargement of the heart from any cause will encroach on the posterior half of the thorax and thus displace the esophagus backward. If the displacement of the heart takes place in pleuropulmonary diseases, the esophagus is usually displaced in the same direction. In pulmonary emphysema or kyphosis, the distance between the esophagus and dorsal spine is increased. In lesions of the mitral valve, the esophagus is displaced to the right and backward. The degree of displacement to the right will help to determine to what extent the left auricle contributes to the formation of the right border of the heart. The backward displacement determines the degree of enlargement of the heart in the anteroposterior diameter. In lesions of the aortic valve the esophagus is displaced to the left and backward. The degree of displacement to the left will help to determine the degree of displacement of the descending aorta to the left. The backward displacement determines the extent of the enlargement of the heart in the anteroposterior diameter and the degree of displacement of the descending aorta to the back. In general enlargement of the heart without aortic dilatation, the esophagus is displaced to the right and backward. In general enlargement of the heart with aortic dilatation, the esophagus is displaced to the left and backward. In congenital heart disease, the displacement of the esophagus depends on the particular defect or defects in the heart and blood vessels. The esophagus is frequently found to be displaced to the right and backward, but seldom to the same degree as in acquired lesions. Frequently the anterior chest wall is found to protrude forward to compensate for the enlarged size of the heart in the anteroposterior diameter. In dilatation of the aorta without cardiac enlargement the esophagus is displaced to the left and backward only behind the great blood vessels. When the heart also is enlarged, the esophagus is also displaced behind the heart. In the presence of aneurysms, the position of the esophagus will help to differentiate between aneurysms arising from the ascending aorta and anterior half of the arch and those arising from the posterior portion of the arch and descending aorta. In enlargement of the heart as a result of dilatation or hypertrophy or both, the esophagus is invariably displaced backward and either to the left or right. In the lateral position the shadow of the heart is seen to extend beyond the shadow of the esophagus and often also the bodies of the vertebrae.

Technic of Making Multiple Urograms—Baker and Lewis in obtaining multiple urograms usually take an ordinary

film of the entire urinary tract prior to cystoscopy. The usual cystoscopic examination is made. Inspection of the bladder is completed. Indigo carmine is injected intravenously and the time of appearance of a concentrated dye is noted. Catheters are passed into the kidney pelvis, nonobstructing catheters being used whenever possible. Specimens are collected under aseptic precautions for laboratory examination. The cystoscope is removed and the catheters are left in place, after which second specimens for laboratory examination are collected. The patient is transferred to a roentgenologic table with the usual fluoroscopic and Bucky equipment. The catheters are now connected by means of metal adapters to syringes containing a known amount of a 15 or 20 per cent solution of skiodan. Under direct fluoroscopic control the pelvis and calices are filled by gravity. When satisfactory visualization is complete the catheters are drawn down to a point about 8 cm from the ureteral meatuses. The roentgen set-up is then thrown in quickly, the catheters are withdrawn and the lower ureters are slowly injected with 1 cc of the opaque medium. The first roentgenogram is taken as the catheters reach the bladder. Two or three other roentgenograms are then made as rapidly as possible. Exposure time varies from one-half to three-fourths second and the time between exposures from eight to ten seconds. A residual roentgenogram is made about ten minutes later. In cases of suspected ptosis a vertical film is taken after the last serial exposure. The roentgenologist must take time to prepare his eyes for proper fluoroscopy. From the fluoroscopic part of the examination much valuable information can be obtained as to fixity of the urinary passages, the type of peristalsis, the relation of extra urinary shadows, the movements of the kidneys with respiration and the passage of the mediums down the ureter. It is frequently necessary to change the position of the catheter by withdrawing it slightly. With practice the roentgenologist is able to estimate accurately by the size and density of the shadow the amount of the opaque medium that flows into the pelvis and calices. At times, fluoroscopy easily answers the query as to why the pyelogram is incomplete. Blurred roentgenograms are due to movements of the intestine, therefore the exposure should be fast enough to stop this peristalsis. Pyelograms for proper detail should be made as rapidly as possible. The entire urinary tract is included in the examination as a routine, a method the authors feel is essential. The present technic of complete examination is attended with much less discomfort than resulted from the old method of unilateral examination in which sodium iodide was used as the opaque medium. Many patients sleep through the procedure on the preliminary dose of morphine, except at the time the catheters are withdrawn.

Determination of Inspiration from the Roentgenogram—Since it is impossible to obtain roentgenograms as a routine in a known phase of respiration in infants and uncooperative patients, Allen and Waltz state that the only way that this can be attempted is through visual determination by the technician. Probably the best results are obtained when the operator assumes a position which places the eyes tangential to the anterior or posterior body wall of the patient closing the primary switch when the abdominal diameters assume the greatest proportions. One half second or less is the limit of time during which an exposure of complete inspiration can be obtained. There may be more air in the lungs at all phases of respiration during a crying spell than during quiet breathing. Therefore, more complete inspiration can be depicted on the plate if it is made during a crying spell. A couch with the tube beneath the patient permits the infant to lie on its back with the plate held to the anterior chest wall by a special frame. The height of the table facilitates a tangential position of the technician's eyes. The following criteria were studied and applied to a large number of roentgen examinations of infants in determining the phase of respiration from the x-ray plate: the angulation of the ribs with the spine, the angle made by the anterior with the posterior portion of a rib at the axillary border, the angle of the outline of the heart in relation to the perpendicular, the change in the position of the clavicles, the position and contour of the diaphragmatic domes, and the magnitude of the cardiophrenic and costophrenic angles. The authors present experimental and clinical evidence supporting the accuracy of the method.

Camphor in Oil in Suppression of Milk Secretion—McNeile employed camphor in oil intramuscularly in 340 cases for the purpose of causing cessation of breast function. The treatment is indicated in weaning and in patients who do not nurse. On the first day two 1½ gram (01 Gm.) doses of camphor in oil are injected, one in the morning and one at night. On the second, third and fourth days one dose is given each morning. The administration should be started on the first day after delivery, if possible. Procedures such as ice bags, tight binders, active catharsis and restriction of liquids should be avoided. If the breasts show any evidence of active function after the fourth day, an injection is given on the fifth and sixth days. The method has increased the certainty of results and has eliminated much drudgery that is always associated with the use of restricted fluids, ice bags, tight binders and active catharsis. In view of the evidence that mechanical factors producing partial or complete blockage of the milk ducts with retention of milk may be a factor in the production of cancer of the breast, in cases requiring cessation of nursing it would seem logical to use an agent that has been shown definitely to cause a cessation of breast function rather than mechanical compression, which in itself causes obstruction to the flow of milk. Camphor in oil given intramuscularly, has a definite inhibiting action on lactation. This effect, as shown by Liegner, is due to a direct action of the drug on the secretory epithelium of the breast. Of the 340 cases cited, an extremely large proportion showed a pronounced beneficial effect. For the suppression of the breast function and the relief of signs of breast engorgement, such as pain, tenderness and heaviness of the breasts, the intramuscular injection of camphor in oil appears to be the most effective form of treatment. Theoretically the use of camphor in oil for the suppression of breast function appears to be more logical than the commonly used methods, and the adoption of such treatment might affect the incidence of carcinoma of the breast following lactation.

Vomiting of Pregnancy—Ainley prefers yellow atrophy of the liver and vomiting of pregnancy to acute yellow atrophy and pernicious vomiting as terms more clearly defining the conditions intended to be identified. Yellow atrophy of the liver, which may be acute subacute or chronic, is an organic disease of toxic origin, may occur either in pregnant or non-pregnant persons, can terminate in death as a result of destruction of vital body tissue and at necropsy always shows a central zonal degeneration or necrosis in the liver lobules. Vomiting of pregnancy, which includes nausea, morning sickness and so-called pernicious vomiting of pregnancy as varying degrees of an identical condition is a functional disease of endocrine origin, occurs only during pregnancy, can cause death from starvation as a result of persistent vomiting, and at necropsy shows the pathologic picture of starvation but no constant or uniform liver destruction.

Pulmonectomy Preliminary Report on Two Cases in Which an Entire Lung Has Been Successfully Removed G A Mason—p 299

Diagnosis of Early Pulmonary Tuberculosis—Wood points out that inspection of the form and movements of the chest are of little help in the detection of incipient tuberculosis. The same may be said of percussion, unless pleurisy with effusion or bronchopneumonic consolidation complicates the picture. Auscultation may be of more value, for a weakening of the breath sounds may be obvious over an area of early infiltration. Fine, moist crepitations—heard best in the inspiratory phase following a short cough—audible over the apex or subapex of an upper or lower lobe are almost diagnostic. But one must not expect to hear them. They indicate very active disease and widespread involvement of the affected lobe. The apex of the lower lobe is favorably situated for auscultation. One is not likely to forget the zone of alarm internal to the spine of the scapula when searching for crepitations, but one is apt to forget that a second zone of alarm is situated internal to the angle of the same bone. If the patient's symptoms, history, manner and appearance and if the physical signs or their significant absence indicate the possibility of tuberculosis, the sputum test, repeated two or three times if necessary, will in the majority of cases prove the diagnosis. If the sputum test is negative, roentgen examination is essential before a final opinion can be given. And if this supplies evidence of tuberculosis, roentgen control will thereafter be essential, for the progress of the case can be studied adequately and its treatment conducted properly only in the light of the information that x-rays provide.

Value of Atabrine and Plasmochin—Williams and Bhattacharyya compared the efficacy of atabrine and plasmochin as prophylactic and therapeutic agents in a population of 234. Prophylactic doses of atabrine and plasmochin were distributed among the line population. Those who developed fever were admitted into the hospital and given a full course of treatment with atabrine and plasmochin. There were fifty relapses, the majority in children less than 2 years of age, showing the absence of immunity in them. The total infection and total incidence of malaria diminished to some extent. This diminution was due chiefly to the reduction of malignant tertian cases, but there was no reduction either in infection or in incidence in benign tertian cases. The authors believe that the real value of an antimalarial drug especially as a prophylactic agent can be gaged properly only when its efficacy is proved in children, and from this standpoint atabrine and plasmochin have failed, in their experiment, to fulfil the somewhat exaggerated claims made. They have however, decidedly better prophylactic value in adults. They believe that atabrine as a therapeutic agent is at least as efficacious as quinine in controlling the clinical symptoms and freeing the peripheral blood from malaria parasites. As to toxicity, it is decidedly superior to quinine. It does not give rise to neurotrophic symptoms and is well toler-

ated by children and also by those who have an idiosyncrasy to quinine as well as by pregnant women. The higher cost of a course of atabrine treatment is somewhat compensated for by the absence of neurotrophic symptoms. As a gametocyticide plasmochin should be used in mass treatment only under proper medical supervision and under suitable conditions.

Dinitrophenol in Dementia Praecox—Finkelman and Stephens selected twelve female dementia praecox patients of the hebephrenic type from 19 to 63 years old and weighing from 135 to 197½ pounds (61 to 89.5 Kg) for investigating the efficacy of dinitrophenol. All but two had been in the institution from two to twenty-four years. All but one of the group were uncooperative in varying degrees at the beginning of the treatment. Cooperativeness increased as the study progressed. Eight patients were given daily, in divided doses, 100 mg of sodium dinitrophenol. The dose was gradually increased to 270 mg. Four patients were started with 60 mg of alpha dinitrophenol daily, which was gradually increased to 300 mg. The dosage was not increased to the maximum if the loss of weight was rapid on a small dose. One patient was not placed on the maximal dosage, because she lost weight rapidly on the initial dose. No change was made in the diet that the patients had previously received. After medication was started, oxygen consumption rates, blood chemistry, including icteric index, cholesterol and blood counts were determined periodically on all patients except the two used as controls. Seven of the patients were under treatment for sixty and four for thirty days. Medication was discontinued in one case at the end of thirty-two days because the oxygen consumption rate had increased to plus 66. The average increase in the oxygen consumption rate (basal metabolic rate) was 37.16. The average loss of weight was 14½/100 pounds (653 Gm) per week. Two patients with a hypopituitary type of fat distribution did not respond to dinitrophenol with either loss of weight or increased oxygen consumption. The oxygen consumption rates returned to the pretreatment values after the administration of the drug was discontinued. The nonprotein nitrogen and icteric index increased and the blood cholesterol decreased during treatment. The icteric index and the cholesterol showed a tendency to return to pretreatment values but the nonprotein nitrogen remained increased. Five patients improved mentally. The increased attention given the patients during treatment cannot be ruled out as having been the chief agent in causing the mental improvement. The reactions of dementia praecox patients to the administration of dinitrophenol together with oxygen should be studied.

Treatment of Prolapse—Robinson states that subinvolution and trauma are the most important factors in the causation of prolapse. Any factor that increases the abdominal pressure, such as constipation, overwork or bronchitis, may cause descent in a woman who is predisposed toward this complaint by congenital or acquired weakness. The author regards operation as absolutely curative only when reproduction has ceased. He believes that prolapse can never be cured by an abdominal operation alone but can nearly always be cured by a vaginal operation. The treatment of prolapse occasionally demands an abdominal as

well as a vaginal operation. The following technic is suggested. An incision is made from two points outside the urethra on each side. These two points are joined by a slightly curved incision, which runs across the vagina below the urethral orifice, and the rest of the incision is completed in the usual way. This technic paves the way for the excision of the bulge, which is generally a conspicuous feature near the urethral orifice, and enables the operator to construct a grid for the support of the urethra and the relief of stress incontinence. The upper vaginal stitches are inserted from side to side, but in the lower part this arrangement is modified by placing the deep stitches laterally and the superficial sutures anteroposteriorly, thus producing a T shaped grid scar in the anterior vaginal wall near the urethral opening, which gives a pleasing esthetic appearance and a good functional result. The uterus is restored to its normal length by excising the redundant portion of the enlarged cervix, and the external os is reconstructed. The uterosacral ligaments are accessible in the posterolateral fornix when the mucous membrane of the vagina has been divided at a distance from the cervix, and their muscular matrix is readily picked up by a needle passed outward and backward in the direction of the sacrum. When these sutures are tied the shortened ligaments pull the cervix upward and backward and restore the uterus to its normal level and position. An oval area is chosen on the outer side of the nymphæ on each side and a portion of tissue corresponding to the displaced labium majus is chosen in accordance with the age, parity and functional requirements of the patient. It is essential that the anterolateral margin of the incision should always be placed on the outer side of the posterior boundary of the nymphæ. By using this method, the reconstruction of the perineal body is greatly facilitated, all sharp angles are abolished and atresia of the vulval outlet is rendered impossible. A further advantage is to be derived from the fact that the length of the vagina is increased rather than diminished.

Action of Extract of Corpus Luteum on Uterus—Morgan found that an active extract of corpus luteum injected into suitably prepared sexually immature rabbits, whether castrated or with intact ovaries, is capable of inducing quiescence of the uterus identical with that which is associated with the presence of normal corpora lutea in the ovaries. The action of corpus luteum extract on the movements of the uterus of sexually mature rabbits is, however, profoundly affected by the presence or absence of the ovaries. In animals in which the ovaries have been removed, treatment with corpus luteum extract inhibits the contractions of the uterus, while in animals with intact ovaries the luteal hormone is almost without effect in altering the activity of the uterus or the structure of the endometrium. It would seem, therefore, that the follicular hormone and the corpus luteum hormone exercise respectively augmentor and inhibitor effects on the motility of uterine muscle, and that the degree of activity of the uterus depends on the relative concentrations of these hormones in the blood. This fact should be kept in mind in cases in which corpus luteum extract is to be employed in human therapeutics. For while relatively small doses of this hormone may be effective in inducing endometrial transformation in cases in which the ovaries are absent it is likely that much larger doses may have to be employed in order to produce effects in cases in which the ovaries are intact and secreting estrogenic substance into the circulation.

Tuberculosis Due to Bovine Type of Tubercle Bacillus—Munro and Walker discuss a case of pulmonary tuberculosis due to the bovine type of tubercle bacillus showing the relentless spread of the bacillus. The significant facts of the case were the widespread distribution of the lesions, the steadily

progressive nature of the disease and the extent of cavitation, all caused by the bovine type of tubercle bacillus. It was difficult from a postmortem examination to determine the paths of spread of the disease. The most grossly affected gland is not necessarily a clue to the portal of entry. The bacillus may enter through any mucous membrane and leave no trace of its entry. Once invasion has occurred the nearest lymph nodes are found to be affected and in the present case there was a history of enlarged cervical glands at 2 years of age while at 7 the enlarged cervical glands were excised. From the present marked thickening of the pleura on the right side, especially over the upper lobe and also the involved cervical glands, the lowest of which are contiguous with the apical pleura, the authors are tempted to infer that the spread to the lung has been a descending lymphatic one. The excavation in the right upper lobe is undoubtedly the oldest pulmonary lesion, and they note that the lesions in the hilar glands seem to be more recent than the lesions in the upper mediastinal glands. Again, the condition in the left lung seems to suggest that the oldest lesion is just under the pleura where there has been an adherent apical cap. The spread to the lung in the upper lobes would seem to be lymphatic and to be a contiguous spread by lymphatic channels through the pleura to the adjacent lung. In the left lung the spread into the lower lobe is suggestive of spread by contiguity from an enlarged tracheobronchial gland, and this is a recent lesion. The same thing is present in the right lower lobe, but there it is not so evident.

Diabetes Mellitus and the Pituitary Gland—Lyall and Innes cite a case of diabetes mellitus which, they believe, illustrates that pituitary lesions and probably most definitely those of the anterior lobe exert a marked influence on carbohydrate metabolism and shows the result of a complicating pituitary lesion in a well established case of true pancreatic diabetes. The manifestations may be slow and rather indefinite in the presence of a healthy pancreas but are more dramatic when true pancreatic diabetes already exists. It would be extremely important to observe the effect of pituitary lesions, whether natural or produced in well established diabetes in man. Marked improvement has taken place in the diabetic condition concurrently with the development of a pituitary lesion. The patient's condition is considered to be clinically analogous to that of an experimental animal in which both the pancreas and the pituitary are destroyed.

*Experimental Reinnervation of Paralyzed Bladder. H. C. Trumble —p. 118

Reinnervation of Paralyzed Bladder—Trumble describes certain experiments on dogs in the course of which a pelvic nerve was divided and its distal segment anastomosed to the proximal segment of either the divided hypogastric nerve or the obturator nerve. The fibers of the donor nerve grew into the distal segment of the pelvic nerve and reached the bladder. Stimulation of the regenerated fibers caused the bladder musculature to contract. In the case of the hypogastric nerve, fibers belong to the sympathetic nervous system, while those of the obturator nerve belong mainly to the voluntary nervous system. The pelvic nerve forms part of the parasympathetic system. This effect on the bladder of stimulation of the regenerated fibers resembled in type that obtained in stimulation of the

normal pelvic nerve. The effect was much better and more certain when an obturator nerve was used than when a hypogastric nerve was employed as the donor nerve. Examination of the branches of the pelvic plexus to the bladder showed that after a successful anastomosis these contained well formed medullated fibers. When the obturator nerve was used as the donor, the fibers were much larger than those seen normally in the twigs to the bladder. The fact that motor effects were observed in the bladder musculature following stimulation of the regenerated nerves cannot be taken as proof that the new mechanism is capable of subserving satisfactorily the act of micturition. After division of both pelvic nerves, dogs in time usually manage to void urine more or less satisfactorily. The fact that the animals in the author's series voided efficiently cannot be taken as evidence that the regenerated nerves had anything to do with it. If in a human being the obturator nerve should be employed as the donor, the subject would possibly be able voluntarily to initiate contractions of the bladder musculature that would serve to expel urine from the bladder. He discusses the indications and contraindications for attempting some such nerve anastomosis in a human being.

Actinotherapy at Tuberculosis Dispensary—Jessel gives the results of treatment in 439 cases of nonpulmonary tuberculous conditions, especially lupus and cervical adenitis, mainly by the use of carbon arc and mercury vapor lamps. Of these patients, 281 were discharged as having the disease in the quiescent form and apparently well. These included seventy-five cases of lupus and scrofuloderma and 182 cases of adenitis, i. e. 91 and 98 per cent respectively of those in the groups who completed a course of treatment. Sixteen were improved and in five cases the condition was stationary. Ninety-seven patients did not complete a satisfactory course of treatment but the condition of most of them was improved. Forty-six patients who were discharged as having the disease in the quiescent form and apparently well received additional periods of light treatment. A return to treatment is sometimes necessary, as relapses are apt to occur whenever any undue strain upsets the balance between a patient's resistance and the bacilli that are lying dormant. Actinotherapy is not a specific cure for tuberculosis, but it does serve in most cases to raise a patient's resistance, thereby enabling him to overcome the disease or to keep it in check. In lupus there is direct action of the rays on the diseased skin, when the Kromayer lamp is used. The interval between the cessation of treatment and the beginning of subsequent treatment in the case of lupus and adenitis with softening was twenty-three months, while for adenitis without softening it was fifteen months.

Conjunctival Symptoms of Measles—De Tomi and his co workers examined directly and by means of the corneal microscope and the fissure lamp the conjunctival mucosa of forty-six children having measles. Subepithelial nodules were observed on the inferior tarsal conjunctiva of thirty-eight of the children. Characteristics of the nodules were their site of predilection limited number, oval form, opal color surrounding red zone and particularly the rapidity of their evolution. They are most apparent during the incubation period of the disease. They grow in size until eruption occurs, after which they become scarcely visible because of intense conjunctival congestion and finally disappear. These characteristics distinguish the nodules from those of any other known form of conjunctivitis. The majority (87 per cent) of the children exposed to the contagion but not contracting the disease did not develop any nodules, but a few did. Several hypotheses are suggested to explain this paradox. The principal one is that the nodules represent a reaction to the virus of measles, not, however, absolutely specific. The authors state in conclusion that measles and other infections may sometimes give only a local reaction instead of the general disease in immunized or refractory subjects.

*Aspecific Primary Peritoneal Serositis and Acute Abdominal Disorders. S Solieri —p 308
Complete Bilateral Duplication of Ureters and Renal Pelvis. G Zappalà —p 316

Peritoneal Serositis and Acute Abdominal Disorders—Solieri says that there is a form of influenzal primary peritoneal serositis simulating acute conditions of the abdomen. Its symptoms are those of influenza, followed by an abdominal crisis with marked pain at the cecal or sigmoid region, fever, and urinary and other disturbances. The study of serous membrane, taken by biopsy, proved that there is noticeable hyperemia of the parietal and visceral peritoneal layers and either a diffuse peritoneal effusion of yellow fluid or foci of exudates at the right or left segments of the colon. Laparotomy with absorption of the fluids by means of absorbent gauze and direct treatment of the serous membrane with 20 or 30 cc. of a solution of colloidal silver has a rapid resolutive action on the abdominal symptoms, which recede immediately after the operation until complete disappearance within four to eight days. At the end of the disease a short period of diarrhea appears. There are no postoperative complications. An associated treatment with salicylates, quinine and caffeine and intramuscular injections of a solution of colloidal silver has a beneficial action on the influenzal and general symptoms, which disappear shortly after the abdominal symptoms. The knowledge of this special reaction of the peritoneal serous membrane to influenza is of great importance in the differential diagnosis of acute conditions of

the abdomen and also in the prevention of abdominal adhesions and perivisceritis, which may result in grave cases if the operation is not performed at an early date. The nine cases reported by the author were observed during an epidemic of influenza.

Surgical Treatment in Articular Fractures P Gómez Cello and C E Bosch —p 625

Quantity of Blood in Circulation in Pneumonia—Levin made determinations of the amount of blood in circulation, by the trypanoth method in twenty-one patients suffering from pneumonia or bronchiopneumonia. The determinations were made during the febrile stage in fourteen patients of the group and both during and after the febrile stage in the remaining seven. The quantity of circulating blood increases during the crisis and returns to normal values at the disappearance of the disease, in cases of moderate intensity. Both the plasma and the globules of the blood increase. The increase of the plasma seems to be due to a displacement of the pH of the blood toward the acid side (with a diminution of the alkali reserve), while the increase of the globules seems to originate in a defective oxygenation of the blood. In grave forms of pulmonary diseases the quantity of blood in circulation is either normal or slightly subnormal. It does not fall, however, to extremely low values even in cases complicated by collapse or in the agonal stage. The amount of blood in circulation was noticeably increased in the agonal stage in a case observed by the author.

Extract of Posterior Lobe of Hypophysis in Treatment of Dysentery—According to Barla-Szabo, the nonspecific symptomatic treatment of dysentery has the aim to reduce the inflammation and the pathologic secretion of the intestinal mucous membrane and to counteract colic and tenesmus. That the extract of the posterior hypophysis reduces inflammatory and secretory processes is known from its therapeutic action in various exanthematous cutaneous changes, but in inflammatory disturbances of other organs this action has not yet been made use of, although it has been determined in animal experiments. The author decided to use the extract of the posterior lobe of the hypophysis to counteract the sanguinolent and purulent stools. He administered it twice or, in severe cases, thrice daily by subcutaneous injection. He treated eight nurslings (from 4 to 12 months old) and eleven children from 1 to 10 years of age. In all these children the dysentery was rather severe, that is they had frequent sanguinolent or purulent stools and their temperature was considerably increased. In five cases the dysentery assumed a toxic character and four of these had a fatal outcome, but even in the fatal cases the blood disappeared from the stool following the administration of the extract. In nurslings the treatment was begun with a dose of castor oil. After that nothing except tea was given for twenty four hours, and then rice gruel. On the third day the feeding was continued with rice gruel and with whey in which from 1 to 3 per cent of flour had been cooked. Breast milk or buttermilk was not given until the fourth day. The injections with the pituitary extract were begun twenty-four hours after the castor oil had been administered and they were continued until the stools became more formed and their blood content lessened. With the exception of one case, this was always accomplished in four days or less. In the children the treatment was similar to that

of the nurslings, except that raw grated apples were given after the tea pause. The extract of the posterior hypophysis influences the inflammatory process, the intestinal secretion and the peristalsis, but it also exerts a favorable effect on the circulation and on the storage of fluid in the tissues. These many points of attack made the extract an ideal symptomatic remedy.

*Experiences with Widmark's Method in Determination of Alcohol in Blood C Hegler —p 288
Decisive Significance of First Roentgenogram for Recognition and Estimation of Necrosis of Lunate Bone H Faust —p 291

Determination of Alcohol in Blood—Hegler asserts that in case of correct withdrawal of the blood specimen and, provided the chemical analysis is done carefully, Widmark's method is reliable. However he admits that in many cases the results of the chemical tests are insufficient without a more exact knowledge of the time and quantity of the alcohol consumption and the clinical manifestations of the alcohol action. He emphasizes that in the practical application of the test the proper preparation of the tubes used is of great importance. Three tubes are necessary for each test, and it is advisable to keep prepared tubes on hand. According to Widmark's rules, they should be prepared with a solution containing 50 Gm of distilled water, 50 Gm. of methyl alcohol, 1 Gm of potassium oxalate and 0.5 Gm of potassium fluoride. The blood specimen should be withdrawn as soon as possible but not sooner than ninety minutes after the drinking of the alcohol. The time of withdrawal should be carefully noted. The tip of the finger or the lobule of the ear is carefully cleansed with a 0.1 per cent solution of corrosive mercuric chloride and wiped with dry sterile cotton. Alcohol, ether, solution of phenol or other volatile organic fluids cannot be used for disinfection of the skin. The author points out that the traffic ordinances prohibit the driving of a motor vehicle by persons who are under the influence of alcohol. For this reason it is important to determine the alcohol content of the blood in case of motor vehicle accidents. In the practical application of the test, the author found that, if the alcohol content of the blood is 0.2 per cent or more, the person is strongly under the influence of alcohol, and even 0.16 per cent makes this quite certain in at least 80 per cent of the cases. He admits that in alcoholic addicts or in persons who have been under the influence of alcohol for several days the alcohol content of the blood is frequently rather low. Persons with delirium tremens often have surprisingly low values. Moreover, the acetone content of the blood may simulate an alcohol content. Nevertheless, the author thinks that in spite of some shortcomings, the test has a distinct value in forensic medicine.

New Method for Recording Electrocardiogram in Three Leads with Two Amplifiers G Kayser —p 274

Diet Deficient in Sodium Chloride, and Inflammation—It was Markees' aim to find a method to determine quantitatively the influence of a salt-free diet on the inflammatory reaction and whether the antiphlogistic action of the restriction of the sodium chloride intake can be proved clinically experimentally. He succeeded in demonstrating experimentally the antiphlogistic action of a diet deficient in sodium chloride. He intentionally restricted the investigation to the sodium chloride action as such, and he did not consider whether it is the restriction of the sodium chloride intake that enables the calcium to exert its antiphlogistic action, whether the sodium ion is alone responsible for the change in inflammation or what part is played by all the other cations and anions in the process of inflammation. The solution of these problems would necessitate numerous other tests. The method employed by him determined the ratio of the sugar content of the bladder and of the blood

This method makes possible the detection of the smallest variations in the intensity of inflammation. This ratio was determined before the salt-free diet was introduced, at the time when the effects of the salt-free diet had reached their maximum and during the time when the salt-free diet was again changed to a normal diet. The curve plotted on the basis of the results of these tests indicates the course of the inflammatory reaction. The test was made on thirty patients, and it was found that under the influence of the salt-free diet the severity of inflammation becomes reduced. That this reduction is the result of the restriction in the sodium chloride intake is proved by the fact that after a return to the normal diet the severity of the inflammation increases again. Another advantage of these tests is the fact that they provide the possibility of connecting a definite idea and meaning with the often used and misused term "umstimmung" (alteration of reaction), for a change in the tendency to inflammation can doubtlessly be considered one form of an alteration of the reaction.

Cirrhosis of Liver and Tobacco—Lickint cites experiments indicating that tobacco is an important contributing factor in the development of cirrhosis of the liver. He thinks that in case of a beginning hepatic cirrhosis, when a change in the diet and an altered mode of life are prescribed, the patient should be urged to discontinue the use of tobacco. In advanced, hopeless cases however, it would be useless to deprive the patients of it. On the other hand it is advisable to give the liver especial attention in all persons strongly addicted to the tobacco habit. Slight enlargement of the liver, its sensitivity to pressure and urobilinuria are symptoms that are quite often manifest in strong smokers of middle age. The author thinks that this is probably due to the fact that the liver is the site of detoxication. Moreover, it has been found that these symptoms disappear when the abuse of tobacco is discontinued. The author admits that tobacco is an etiologic factor only in some of the cases of hepatic cirrhosis; nevertheless, it would be wrong to disregard entirely the part played by tobacco in the development of this disease.

Primary Lymphogranulomatosis of Lung Case II W. Sachs —p. 271
Origin of Pulmonary Edema and of Vagus Pneumonia F. Grogler —p. 274

*Multiple Sclerosis a Metatuberculosis II. Gerhartz —p. 280

Oral Infection with Lymphogranuloma Inguinale—Bezecky and Sagher relate the history of a man aged 46, who four weeks previous to obtaining medical aid developed an ulceration of the tongue and a week later a swelling of the lymph nodes of the left side of the neck. The primary lesion and the involvement of the regional lymph nodes made a syphilitic infection likely, but the tests for syphilis gave negative results, while the Frei test was positive. The anamnesis disclosed that the patient had had intercourse with a woman who four years before had a disorder of the inguinal lymph nodes. It appears that a bubo had developed, had become soft and was incised. The localization of the lesion in the man corresponded to the anamnestic statements about the type of intercourse. In the conclusion the author emphasizes that caution is necessary in declaring a patient with lymphogranuloma inguinale cured, for in this instance the woman was apparently cured, and she again became a source of infection four years later.

Multiple Sclerosis a Metatuberculosis—Gerhartz observed a relationship to tuberculosis in fifteen cases of multiple sclerosis that is in all cases examined for such a connection. The specific tuberculosis reaction according to Besredka was positive in the blood of nearly all these patients in spite of the fact that there existed no clinical manifestation on the basis of which a positive reaction could have been expected for as a rule, the reaction is positive only in active tuberculosis. Even in the two cases in which the test was negative it was possible to demonstrate a predisposition to 'inflammatory tuberculosis'. However, the author considers that the positive outcome of the specific test for tuberculosis in the cerebrospinal fluid of a patient with multiple sclerosis is the most convincing proof of the metatuberculous character of multiple sclerosis.

*Physiologic Therapy of Angina Pectoris by Means of Musculo-Adenosinephosphoric Acid W. Sommer —p. 292

Prognosis of Carcinoma—Hintze points out that the further course can be foretold with considerable certainty in carcinoma, while prognosis is extremely difficult in sarcoma. Carcinoma grows slower and more regular than sarcoma, and the author thinks that this difference in the two types of tumor is the result of their different origins, carcinoma deriving from epithelial and sarcoma from mesenchymal tissues. The author emphasizes that carcinoma begins always as a local disease focus. The prognosis is primarily dependent on the size and the extension the growth has reached before the patient consults a physician and submits to adequate treatment. Other factors that are important for the further course are the localization, the type of growth and the histologic character of the tumor, but also the patient's age and his general constitution. The treatment must take account of all these factors and, in selecting the most suitable method, must aim at a complete removal of the tumor. The control examination by the physician at regular intervals is likewise highly important for a favorable prognosis.

Strophanthin in Treatment of Angina Pectoris—Zimmermann shows that the introduction of strophanthin into the treatment of angina pectoris produced a great change in the treatment of this much feared disorder. Strophanthin makes it possible to reduce the danger from attacks, and, even in a patient in whom the primary disease progresses, it is possible to produce a condition that will enable him to be fairly comfortable. The patient's dependence on syringe and physician represents a disadvantage. The fear that the early use of strophanthin would result in habituation, so that in case of real danger the heart would not respond to the treatment, is unjustified, because habituation to digitalis bodies is unknown. Moreover, strophanthin is not the most powerful remedy but the most suitable for these cases and its early use prevents a great danger.

Diagnosis of Latent Phlebitis in Lower Extremities—Schmidt states that Meyer's report on deep-seated phlebitis as an example of a focal infection and as a causal factor in rheumatism induced him to study the problem of latent phlebitis. As indicated by the term latent the symptomatology is rather scanty, but the author found that the determination of the pressure points described by Meyer is a valuable aid in the diagnosis. To detect these pressure points, the patient should be lying on the back with the knees bent in such a manner that the musculature is completely relaxed. The examiner should grasp the lower part of the leg with the entire hand and press with the thumb from below the posterior tibial vein against the median edge of the tibia. In the middle portion of the leg this pressure is exerted in the same manner directly beside the edge of the tibia and in the upper third two fingerbreadths from the median edge of the tibia. If areas of muscular hardness should be present along the course of the posterior tibial artery, this is of differential diagnostic significance, but the author thinks that it is probably a rare occurrence. Symptoms highly important for the differentiation of latent phlebitis and muscular myogelosis are the exactly contradictory disturbances during walking and standing. In myogelosis walking increases the pain, while in latent phlebitis walking eases the discomfort and the pains are most severe when the patient is standing. In doubtful cases it is better to assume the existence of a latent phlebitis, for the bandages that are applied for the treatment of latent phlebitis have no harmful effect on a possible myogelosis while massage given in case of a myogelosis would be decidedly harmful for a latent phlebitis. The author admits that the pressure points may be present also in cases of thrombo-angitis obliterans but he thinks that in the more advanced stages of this disorder the differentiation will make no difficulties.

Therapy of Angina Pectoris—Sommer is of the opinion that muscular adenosin phosphoric acid is a substance that presents the formerly so-called cardiac hormone preparations in pure form. When this substance was administered in adequate dosage, the results were much better than those produced by the older preparations. Animal experiments disclosed that the intramuscular injection of muscular adenosin phosphoric acid produces a prolonged increased blood perfusion of the coronary arteries and consequently a better oxygen supply for the cardiac muscle. The author's clinical observations indicate that as a physiologic therapeutic agent of angina pectoris the preparation gives good service.

*Problems in Treatment of Diabetes Insipidus with Extract of Posterior Lobe of Hypophysis F Mainzer—p 101

Functional Disturbances of Liver—Mjassnikow shows that the infectious, toxic disturbances of the liver, which are usually referred to as cirrhosis, can be classified in two groups: the forms in which a number of functional disturbances exist (disorders of bile secretion and of the protein and lipid metabolisms) and the forms in which such disturbances are not present. It can be observed that the chronic hepatitis with hepatic insufficiency are etiologically related to processes in which the epithelial tissues of the liver are the object of the toxic action (acute hepatitis, alcoholism and syphilitic intoxication), whereas the chronic hepatitis without hepatic insufficiency are etiologically related to processes localized in the interstitial hepatic tissue (gummatous syphilis, tuberculosis, periangiocholitis). Thus chronic hepatitis with hepatic insufficiency is the result of an involvement of the hepatic parenchyma (chronic parenchymatous or epithelial hepatitis) while hepatitis without functional disturbances is the result of a disorder of the interstitial tissues of the liver (chronic interstitial or mesenchymal hepatitis). In some cases of interstitial hepatitis, changes in the epithelial cells of the liver may develop later and these changes are then accompanied by functional disturbances on the part of the liver. It is essential to differentiate the different stages of the disease process in the clinical pictures of the various forms of hepatic disorders. During the first stage the degenerative or inflammatory processes predominate and during the second stage the increase in the connective tissue of the liver reaches a considerable degree. The icterus that develops in hepatic cirrhosis is a manifestation of an impairment of the liver cells.

Extract of Posterior Hypophysis in Treatment of Diabetes Insipidus—Mainzer discusses the problems encountered when diabetes insipidus is treated by the nasal administration of the extract of the posterior hypophysis. He obtained favorable results in five cases in which the hypochloremic disturbances predominated. In order to measure the efficacy of the extracts, the so-called water equivalent was introduced. The water equivalent is that quantity of fluid by which the fluid exchange is reduced under the influence of one Voegtlin unit for each kilogram of body weight. It is best to administer quantities of extract that are just adequate to effect complete compensation, that is, an amount which if decreased would result in an increase of the fluid exchange but if increased would cause no further reduction in it. This amount fluctuated in the author's cases between 0.2 and 35 cc. per kilogram of body weight. Even in the same patient, various amounts of extract may be required at different times. There are cases in which the efficacy of the extract is comparatively slight but complete inefficacy was never observed. The quantities of extract varied between 50 and 280 Voegtlin units; that is, the doses were several times as large as in parenteral administration. The administration of the required doses caused no undesirable complications. However if the dose becomes excessive drawing pains in the head and dizziness may result. In two cases the author observed that the establishment of medicinal

compensation resulted in a considerable loss in weight, whereas the disturbance was accompanied by a fluid storage up to 5 Kg. This contradicts the widely held opinion that in diabetes insipidus a dehydration exists which explains the feeling of thirst. If the extract is administered through the nose, the thirst becomes reduced in from ten to fifteen minutes and, after compensation has been established, this effect of the extract persists for from eight to ten hours, following cessation of the medication. After prolonged nasal administration there often results an irritation of the nasal mucous membrane which makes the preparation ineffective, however, a pause in the medication often reestablishes the former condition. Prolonged treatment may improve the diabetes mellitus, in that gradually smaller quantities suffice to produce compensation.

Histamine and Inflammation—According to Loos it is generally believed that the inflammatory reaction is due to substances formed in the irritated or damaged tissues. These substances, similar to the hormones, are formed only in minute quantities. They differ from hormones in that their formation is not dependent on special organs but they may develop in all tissues. Histamine seems to play an important part in these tissue hormones and it was the author's aim to demonstrate the presence of histamine-like substances in the focus of inflammation. His studies disclosed a considerable increase in the histamine-like substances. At any rate, he considers it probable that a close relationship exists between histamine and inflammation.

Water-Wheel Murmurs and Artificial Pneumothorax

—Hirsch and Sauser give the histories of two patients in whom water wheel murmurs developed during artificial pneumothorax therapy. In the first case the murmur was the result of the bursting of a superficial, thin walled cavern into an artificial pneumothorax. The cavity collapsed only partly, because two strands of adhesions stretched it upward and outward. Ten days later during a severe attack of coughing, the patient had the feeling as if something were torn in the chest and after that the water-wheel murmur was perceptible. The author thinks that in the course of the attack of coughing the pressure within the bronchial system connected with the uncollapsed cavity increased to such an extent that it burst into the pneumothorax space. Thus a valvular pneumothorax was formed, the pressure of which increased with every breath. It cannot be doubted that the bursting of the wall of the cavern resulted in the rupture of blood vessels. These ruptured vessels sucked up air from the pneumothorax space, and the blood stream carried the air into the right side of the heart where the water-wheel murmurs were elicited. Since apparently a large amount of air had entered the right side of the heart air was forced also into the lung and under growing dyspnea death finally resulted. In the second case it is probable that a thoracic vein was injured by the pneumothorax puncture and that the violent movements of the patient during an attack of coughing opened the injury and air entered either from the newly formed pneumothorax or from the pneumothorax apparatus. The air reached the right side of the heart, where the water-wheel murmur was then formed. Since symptoms of air embolism developed at the same time and since later a hemiplegia developed air must have entered also into the left side of the heart and thus into the arterial portion of the circulation. In this case the phenomenon terminated after from fifteen to twenty minutes. The authors conclude that these two cases prove with certainty that the water-wheel murmur develops in the right side of the heart.

*Treatment of Vomiting of Pregnancy by Means of Adrenal Cortex Extract W Stemmer—p 456
Pathogenesis and Therapy of Eclampsia B Archangelski—p 458
*Allergic Theory of Pregnancy Toxicoses B Jegorow—p 465

Treatment of Vomiting of Pregnancy—Stemmer followed the suggestion of Kemp and treated women who during pregnancy were troubled with attacks of vomiting, by giving them intramuscular injections of adrenal cortex extract. He administered daily up to three ampules (1 cc. each). In the milder cases of nausea and vomiting he gave the injection during the consultation hour, but the more severe cases were hospitalized. The length of time during which the adrenal cortex therapy has to be continued varies in the different cases. Psychotherapy was omitted whenever adrenal cortex extract was administered, and yet several cases presenting psychotic symptoms responded favorably. The author cites the case of one woman who complained of indistinct pains in the right thigh, which proved refractory to several therapeutic measures but finally disappeared when the adrenal cortex extract was given because nausea and vomiting had set in. He is unable to explain the appearance or the disappearance of the pains, but he points out that in Addison's disease painfulness of the lower extremities has been noted. He also observed a case of general debility and pains in the joints and in the back, in which all these symptoms disappeared after treatment with adrenal cortex extract. He assumes that there may be several forms of adrenocortical insufficiency or several hormones of the adrenal cortex. According to some investigators, civitamic acid is an active principle of the adrenal cortex. In trying to explain the mode of action of adrenal cortex extract in the vomiting of pregnancy, the author suggests that during pregnancy the blood cholesterol is increased and that this is probably the result of a greater fat metabolism. He points out that Anselmino and Hoffmann ascribe the vomiting of pregnancy as well as acetoneuric vomiting of children and adults to an increased elimination of the anterior hypophyseal hormone of the fat metabolism. It seems that the increased secretion of this metabolic hormone is counteracted by adrenal cortex extract. In view of this theory, it would perhaps be justified to try adrenal cortex extract also in acetoneuric vomiting.

Allergic Theory of Toxicoses of Pregnancy—Jegorow maintains that the changes which the organs and tissues undergo during pregnancy are an allergic reaction to the fetus and its membranes. The pregnant woman receives parenterally during her nine months of pregnancy increasing doses of protein and other substances that originate in the fetus, its membranes and the placenta. In response to this, the pregnant organism becomes sensitized. The early and late toxicoses of pregnancy

develop not as a result of an intoxication with the waste products of the fetal metabolism but because the organism of the pregnant woman produces an allergic reaction in response to these substances. The allergic theory of the toxicoses of pregnancy is corroborated by the fact that it was possible to produce in pregnant women positive allergic skin reactions and immunobiologic allergic reactions. The author thinks that, in addition to the symptomatic treatment of the toxicoses of pregnancy, a causal therapy, a desensitization, should be tried. He thinks that the efficacy of the dietetic treatment of the toxicoses of pregnancy, particularly of eclampsia, is due to the fact that the dietetic treatment represents a desensitization.

Osteomyelitis of Symphysis Pubis in Children V A. Shturm—p 139

Radical Intervention for Tuberculous Coxitis—The conservative treatment of tuberculous coxitis, according to Gelikonova, is frequently inadequate in bringing about complete healing of the local process and restoring the working capacity of the patient. On the other hand, extensive resections at the height of the disease aggravate rather than improve the results. The proposition advanced by Professor Korney that the conservative treatment of tuberculous gonitis be followed by radical removal of localized lesions of the joint is likewise applicable to tuberculous coxitis. Such interventions are applicable to older children not as an extreme measure but as the last step at the end of conservative treatment. Persistent preoperative as well as postoperative treatment is obligatory. There were no fatalities resulting from the thirty three radical interventions for quiescent tuberculous coxitis. Exacerbation or extension of the local process has not been observed in any of the twenty-two discharged patients. Gravitation abscesses must be emptied and in isolated stubborn cases may be extirpated in the course of the operation before the joint is opened. Arthrectomy and periarticular osteoplastic arthrodesis are useful supplements to resection.

Operative Treatment of Syringomyelia—According to Yuzhelevskiy, Poussep's operative treatment of syringomyelia consists of laminectomy, exposure of the meninges of the cord and establishment of communication between the central canal of the cord and the subarachnoid space. The incision in the cord is made lateral to the posterior commissure. The mechanism of action is not clear. Poussep's concept that it diminishes the pressure within the central canal is not borne out by comparison of clinical symptoms and postmortem observations. Direct manometric observations demonstrate that the pressure in the syringomyelic portion of the canal as well as in the corresponding subarachnoid space is within normal limits. On the basis of their own twenty-three cases (E. P. Gesse's clinic, Leningrad) and eighty-one cases reported in the literature, the author considers the immediate results of the Poussep procedure generally beneficial. Complete cure has never been observed, the improvement being limited to some of the symptoms. The improvement obtained was not greater than that observed with conservative measures or even from a temporary rest from occupation. The improvement from the operation of syringomyelostomy is not permanent. It terminates in the majority of the cases after a few months or weeks. The operation does not arrest the progress of the disease. Numerous manometric observations on the pressure of the cerebrospinal fluid of the involved portions of the cord and of the corresponding subarachnoid area show that it is within normal limits. Recent clinical observations and microscopic studies fail to provide a theoretical reason for the Poussep operation. The author concludes that the operation is rather contraindicated when the disease runs a chronic mild course. An attempt to alter its course may be justified when the disease presents a stormy character.

WATER INTOXICATION

REPORT OF A FATAL HUMAN CASE WITH CLINICAL,
PATHOLOGIC AND EXPERIMENTAL STUDIES

FERDINAND C. HELWIG, M.D.

CARL BRYANT SCHUTZ, M.D.

AND

DWIGHT E. CURRY, M.D.

KANSAS CITY, MO

Recently attention has been called to the dangers incident to the forcing of fluids, particularly in post-operative cases. De Takáts¹ mentions overloading of the circulation in cardiac weakness, production of general anasarca in Bright's disease, and accentuation of cerebral edema in concussion of the brain. However, one of the most interesting complications, which has not been mentioned, is the possibility of so-called water intoxication. Rowntree² in 1923 called attention to this phenomenon in man and reported a number of experiments in which he produced this condition in animals. He first noted what he interpreted to be a condition of water intoxication in a number of patients suffering with diabetes insipidus to whom he and his associates had given repeated doses of solution of pituitary. These patients had been in the habit of consuming from 8 to 10 liters of water by mouth daily without any untoward effects. When, however, they were given solution of pituitary and continued to consume their usual quantity of water, headache, nausea, asthenia, incoordination and a staggering gait rapidly developed, and in one instance he states that the patient's symptoms became "extremely alarming." This observation led Rowntree² to administer large amounts of distilled water by mouth to animals in an attempt to produce symptoms similar to those observed in the patients mentioned. In these experiments he was able to cause a definite and consistent series of symptoms characterized by asthenia, followed by muscular irritability, convulsions, salivation and finally death which he believed to be due to water intoxication. Since these animals could be relieved of their symptoms and in fact saved from death by the administration of salt solution, he concluded that the pathogenesis of the intoxication was probably due to an upset in the salt-water balance. Moreover, he made the interesting observation that it was impossible to induce water intoxication in animals that had been given 10 per cent solution of sodium

chloride immediately before the administration of the water. In this regard it might be mentioned that both Moss³ and Brockbank⁴ have noted extreme muscular cramps in workmen who perspired freely and drank large quantities of water. These cramps were relieved at once simply by drinking salt water.

Knowing of these instances, we became interested in the subject of so-called heat cramps as a possible industrial hazard and communicated with a well known industrial surgeon who has charge of a large number of men working under high temperatures. He wrote as follows:

In reply to your question as to the use of salt tablets among workers subjected to high temperatures, I wish to state that for several years we have placed 5 grain (0.3 Gm.) sodium chloride tablets in readily accessible places throughout the plant so that several times a day a worker may avail himself of these tablets. Before using these we noticed from fifty to 100 cases of dizziness, weakness, palpitation, nausea or vomiting and headache and a common complaint was 'inward nervousness' among the men. At this time, and since we have been using sodium chloride tablets, not over one or two men enter the first aid station with the above complaints, and almost invariably these men admit of not using the salt tablets. These results are of consequence inasmuch as several thousand men are involved, although the men are not required to take the salt tablets except where they are exposed to unusual temperature. Most of the men who have been employed in a similar type of work are familiar with the symptoms they get when they do not take salt tablets and actually will come into the first aid station to have them dispensed if they are not readily available.

The foregoing clinical observations strongly suggest a close association between water balance and the chloride of the blood.

Of great interest also is the observation of Rowntree that, in all his cases of experimental water intoxication, cerebral edema was noted. He felt that the convulsive seizures and subsequent death of the animal were due directly to the cerebral edema. He substantiated this conclusion by preventing the appearance of the convulsions by decompression of the skull.

So far as we have been able to determine from a search of the literature, there has been no fatal human case of so-called water intoxication nor had it been possible consistently to produce the phenomenon in animals by proctoclysis. There are, however, on record a number of instances in which definite clinical manifestations of water intoxication were observed. Thus, Priestly, McCallum and Benson⁵ noted after drinking

a rather large amount of water definite nervous manifestations typical of the early stages of water intoxication Similarly, Amberg and Austin,⁵ during experiments on skin elasticity in which they drank 3,000 cc of water in a period of twenty minutes, noted the development of such severe muscular twitchings

Fig 1—Postoperative course with fluid intake and output with clinical data

that they were unable to make elastometric measurements In addition, Miller and Williams⁵ observed the typical symptoms of severe water intoxication in patients with nephritis on whom large quantities of fluids had been forced

Recently we have observed a case in which death apparently resulted from water intoxication wherein the patient absorbed 9,000 cc of tap water by proctoclysis, and we have been fortunate in being able to produce identical symptoms and pathologic changes in seven

Fig 2—Oil immersion photomicrograph of liver biopsy taken during the operation Note marked cloudy swelling and sinusoidal obliteration

consecutive rabbits by the administration of large amounts of tap water by rectum

REPORT OF CASE

History—A well nourished woman approximately 50 years of age had a long history of gallbladder disease. Laboratory examination before operation was essentially negative At

operation, a thickened gallbladder containing a number of stones was removed without difficulty A small piece of the liver was removed for microscopic examination, and a Penrose drain was inserted in the gallbladder fossa For the first twenty-four hours following the operation, the patient's condition was excellent Immediately following the operation, 1,000 cc of tap water proctoclysis was started, figure 1 records the amounts and the time of administration of fluids, together with important clinical data

Pathologic Changes—The gallbladder was not enlarged. Its walls were slightly thickened and it contained about 200 small mulberry stones The mucosa was pale and the trabeculae were flattened Microscopically, the walls were moderately thickened and a few scattered round cells were found in the interstitial tissue The piece of liver showed a very striking parenchymatous degeneration The liver cells were swollen and remarkably granular The sinusoids were almost completely obliterated by the swollen parenchymatous cells and the liver cells appeared to be packed closely together throughout the entire section Inflammatory cells were absent (fig 2)

Necropsy—This was performed within one hour after death and neither rigor mortis nor livor mortis was present. The

Fig 3—Oil immersion photomicrograph of a so-called corpus amylaceum in the lung Observe fine pigment granules and adherent cells

body was still quite warm External inspection was not noteworthy Edema was not present An old healed midline surgical scar below the umbilicus was seen and a freshly sutured wound was present in the upper right rectus region This wound was in good condition and one rubber drain was protruding from it Inspection of the abdominal cavity revealed that the gallbladder fossa was hyperemic and the liver was somewhat enlarged It weighed 1,800 Gm and showed a slick, moist cut surface with quite indistinct lobulation The bile passages were patent throughout. The stomach contained about 600 cc. of fluid and was dilated with gas The bladder also was somewhat distended and contained about 400 cc of urine. The descending and sigmoid colons were almost spastic, while the remainder of the bowel was of about normal caliber The appendix uterus and adnexa were absent and no adhesions were present in the pelvis or the right lower quadrant.

In the chest, the organ relationships were normal, the lungs were freely crepitant and no excess of fluid was present in the pleural or pericardial cavities Careful examination of all the viscera revealed no abnormalities of importance not previously mentioned.

The cranial cavity was then investigated The scalp and skull presented nothing of pathologic importance When the skull cap was removed the dura mater was found to be

stretched tightly and the underlying brain was of striking appearance. The subarachnoid space seemed to be completely obliterated and the pia arachnoid was almost bloodless. The cerebral convolutions were very much flattened and the sulci appeared in most instances to be completely obliterated, being seen as fine lines coursing over the cerebral hemispheres. No subarachnoid fluid was present and the brain surface presented a rather dry appearance. After the brain was removed it was found to be uniformly swollen in all diameters and gave the impression that it had been crowded into the cranial vault, having an appearance not dissimilar to internal hydrocephalus. When the ventricles were opened, however, instead of being dilated they seemed to be actually reduced in diameter and a maximum of 2 cc of clear fluid lay on the floor of each ventricle. The choroid plexus contained a cyst about 20 mm in diameter in the left lateral ventricle and the whole plexus appeared swollen and edematous. Cross section through the brain showed a smooth homogeneous "wet" appearing surface and in the cerebral cortex the outlines between the white and the gray matter were much more indistinct than normal. Careful inspection of all the vessels showed no noteworthy alteration. No hemorrhages or foci of encephalomalacia were seen. The brain weighed 1440 Gm.

Fig 4—Oil immersion photomicrograph of liver post mortem. The liver cells are swollen and granular. The sinusoids are dilated and are filled with small rounded and oval bodies suggesting red cells that have lost their hemoglobin.

Microscopic Changes—The lungs, liver, brain, kidneys and bowel were the only organs showing any alteration from the normal. The lungs showed many rather large corpora amylacea in the alveoli, which in many instances showed a few ragged cell fragments clinging from their outer borders and many of them were seeded with brown pigment granules (fig 3). Some of the alveoli contained a small amount of pink homogeneous precipitate suggesting fluid and the interalveolar capillaries were distended with red cells.

The liver showed a rather advanced cloudy swelling yet many of the sinusoids were quite dilated and filled with small rounded and oval bodies about the size of a red cell with sharply circumscribed outlines and for the most part they were very faintly reticulated but otherwise colorless somewhat suggesting red cells that had lost their hemoglobin (fig 4).

The kidneys, aside from a moderate grade of cloudy swelling of the more highly differentiated tubular epithelial cells were essentially normal.

In the stroma of the mucosa of the large bowel scattered polymorphonuclear leukocytes were found.

The brain showed an apparent increase in vacuolization of the stroma, with what appeared to be an increase in the caliber

of the perivascular and perineural spaces (fig 5). In some areas a few round cells were present in the Virchow-Robin spaces and the brain tissue surrounding the external limiting membrane of the perivascular spaces was quite edematous and

Fig 5—Section of brain of the patient under low power. Perivascular and perineural spaces show dilatation.

frequently showed a rather poorly defined, faintly reticulated, false space immediately adjacent to the limiting membrane (fig 6). Some of the blood vessels contained masses of amorphous reddish brown material suggesting hemolyzed blood. The choroid plexus was distinctly edematous. The ependymal

Fig 6—Oil immersion photomicrograph of brain of the patient. Observe dilatation of Virchow-Robin spaces with an infiltration of leukocytes. Peripheral to the outer limiting membrane of the Virchow-Robin spaces a false space is seen traversed by glial fibrils and the adjacent brain substance is highly vacuolated.

cells were swollen and vacuolated and were undergoing proliferation and in many areas, desquamation (illustrated in figures 7 and 8).

There were scattered leukocytes mostly lymphocytes present in the swollen edematous, subependymal, connective tissue and

in some areas the subependymal accumulation of fluid was so striking as to leave large areas between the layers, producing in some fields a picture suggestive of cystic degeneration (fig 9) The ependymal lining of the ventricles showed similar

his experimental animals that died of water intoxication, together with the fact that our patient had absorbed some 9,000 cc of water, suggested the possibility that her death might have been due to water intoxication. We therefore conducted a number of experiments on rabbits in an attempt to reproduce the clinical and pathologic picture shown by our patient, by the administration of water by proctoclysis.

Rowntree² stated in the report of his experiments on water intoxication that he was unable to produce water intoxication by the administration of water by bowel, although he did mention that Greene had apparently been successful in one instance. A search of the literature failed to reveal a report of experimental water intoxication produced in this manner. We felt, however, that, if we were correct in our assumption that our patient died as the result of the excessive absorption of water, we should be able to reproduce her symptoms by administering tap water in the same manner as that in which it was given to her.

Fig 7—Oil immersion photomicrograph of choroid plexus of the patient. There is proliferation, desquamation, swelling, and vacuolization of the ependymal cells.

changes to those seen in the choroid plexus, and the underlying brain substance was distinctly edematous, showing a rather striking vacuolization (fig 10).

Fig 9—Section of choroid plexus of patient under low power showing a very striking subependymal accumulation of fluid.

Fig 8—Oil immersion photomicrograph of choroid plexus of patient. In addition to the ependymal change, subependymal edema is quite striking.

Special fat stains were employed on all the organs to eliminate fat embolism. No intravascular droplets were found in any of the viscera.

ANIMAL EXPERIMENTATION

The striking similarity of the clinical manifestations of the patient on whom these observations were made to the symptoms and changes observed by Rowntree in

Our technique was extremely simple. Healthy young rabbits, weighing approximately 1,000 Gm., were given 50 cc of ordinary tap water by rectum through an ordinary rubber catheter, at intervals of one-half hour. In the first two animals, no further preparation was made, but since we found that in the third animal we were at first unable to produce intoxication in this manner, we withheld all water and food from subsequent animals for a period of two days before water was administered.

Prior to the experiment, blood counts and blood chemistry studies were made on all animals. These were compared to similar studies made on the animals after the full development of the toxic symptoms. During the experiment the rabbits were placed in metal cages and all urine was collected and measured.

Seven animals were used and in each we were successful in our attempts to produce the picture of water intoxication. In all instances a complete necropsy and histologic studies were made.

Immediately following the death of two of the animals a chemical analysis of the muscles, liver, kidneys and brain was made for the chloride content by one of us (D E C)

Fig 10—Oil immersion photomicrograph of ependymal lining of the lateral ventricle of the patient's brain. Ependymal swelling and marked vacuolization of the subependymal brain tissue is striking

In every animal on which the experiment was performed, the clinical manifestations were exactly similar. Following the injection of the first 300 to 400 cc of tap water by rectum, the only change that was noted was a marked increase in the urinary output of the animal and a definite decrease in the specific gravity. After approximately 500 cc of tap water had been given, the urinary output decreased somewhat and the rabbit began to salivate. Soon thereafter the rabbit became restless and fine fibrillary twitchings of the ears and muscles of the extremities were noted. Within the next hour, with the injection of an additional 100 cc. of water, these fibrillary twitchings were replaced by clonic convulsions and marked opisthotonos (fig 11), dilatation of the pupils, and a marked decrease in urinary output. Whether injections were stopped at this point or not, the convulsions continued, becoming more prolonged and more severe. The typical convulsions began with retraction of the head and stiffening of the extremities. Within a second or two, however, this "frozen state" was replaced by rapid, rhythmic movements of the extremities which are best described as a "running motion". The latter phenomenon continued for from one to three minutes, when a sudden and complete relaxation of the entire body took place, only to be quickly succeeded by another convulsive seizure. As death approached, the rest periods became less frequent and of shorter duration, so that just before death the animal was in a continuous state of convulsion. Death in all instances except the animals that were killed during a convulsion, occurred in the midst of a convulsion.

Studies of the blood before and after the experiment revealed a number of interesting changes. There was a consistent decrease in the blood chlorides, ranging from 100 to 240 points. The blood nonprotein nitrogen was inconsistent in some instances remaining

unchanged, in others increasing as high as 100 mg per hundred cubic centimeters. The carbon dioxide combining power of the blood plasma was decreased in those rabbits on which determinations were made, but these studies were not carried out except in two animals. In accordance with the results found by Rowntree, there was a consistent blood dilution, as evidenced by a decrease in the hemoglobin and red blood cells.

In comparing the reactions of our rabbits in which an excessive amount of water was injected by rectum to those described by Rowntree in which an excessive amount of water was administered by mouth, it is evident that they are strikingly similar. It is our opinion that so-called water intoxication has been produced in both series. The pathologic changes in our animals are also of interest in that they not only bear out the same general changes mentioned in the examinations made by Wilson for Rowntree but in addition we have observed some changes that he did not mention.

PATHOLOGIC CHANGES IN EXPERIMENTAL ANIMALS

In the experimental animals that were examined at necropsy, no striking gross alterations were observed. The stomach contained a great deal more fluid than normal. In a few instances the bladders contained considerable clear urine, while in others they were empty. There was a rather uniform moderate constriction of the large bowel and the cecum seemed to contain more fluid than normal. The livers in all instances showed a shiny moist cut surface. The brains all appeared to be swollen, the normal markings were somewhat obscured, and the surface vessels were usually bloodless. It was not possible to say accurately whether the lateral ventricles were diminished in size, but when compared to normal rabbit brains we gained the impression that they were.

Microscopic examination of the viscera showed fairly uniform changes in the brains of all animals. When compared to normal brains in frozen section to eliminate shrinkage as nearly as possible, there seemed to be definite widening of the perineural and perivascular spaces, and the intercellular stroma was definitely vacuolated throughout (figs 12 and 13). Degenerative changes in the nerve cells could not be demonstrated by Nissl's stains.

In all instances, the choroid plexuses were the seat of a distinct increase in vacuolization with swelling and

Fig 11—A beginning of convulsion showing opisthotonos and extension of extremities. B height of convulsion. The extremities are extended in clonic contraction. Salivation is profuse. C frozen state. Marked opisthotonos and extension of extremities in spastic type of muscular contraction. These pictures were taken from 16 mm. moving picture films which accounts for the blurring.

subependymal edema The ependymal lining of the ventricles were likewise vacuolated, swollen and desquamating The brain tissue showed vacuolization of the stroma, which seemed to be increased considerably above the normal In all respects the changes in the brains of the experimental animals closely simulated those seen in the fatal human case

Cloudy swelling was uniformly present in the livers of all animals, in some instances to a very advanced

Fig. 12—Section of brain of rabbit under low power showing widening of the perivascular and perineural spaces

degree, and in two instances there was a definite concomitant widening of the sinusoids, which contained a stringy faintly staining precipitate containing red cells In many instances these red blood cells were swollen and had lost most of their hemoglobin pigment, suggesting hemolysis (fig 14) In some cases edematous fluid was present in the pulmonary alveoli, but this was by no means generalized

CHEMICAL STUDIES

Analysis of body tissue for chlorine content was performed on two experimental animals as well as on two controls Briefly, the method consisted of digestion of fresh tissue with concentrated potassium hydroxide and heat This resulting solution was neutralized with nitric acid Silver nitrate was added and the chlorine precipitated in the form of silver chloride, from which the determination of chlorine was calculated

The results of this analysis were of interest and very suggestive, although there was considerable variation in the chlorine content The chlorine content of the brain showed the greatest reduction in the water intoxicated animals, showing nearly 50 per cent decrease The liver showed a rise in chlorine content and in all other tissues a decrease The heart was least affected and remained almost the same in every rabbit

This work was performed once before by Dr Misawa⁶ He used desiccated tissue and his results were correspondingly less in variation, since the water of the intoxicated animal was not a factor in his

weights However, the results of his work and ours were relatively the same In the water intoxicated animal he found that "there was a reduction of chloride in all the tissues of the body save the liver, as well as the blood The reduction was greatest in skeletal muscle, where it amounted to a loss of 51 per cent, and it averaged 20 per cent in other tissues except in the liver, where a 10 per cent increase occurred" The fact that we used fresh tissue instigated the greater water weight in the water intoxicated animals as compared to the normal animals and naturally resulted in a larger weight difference than that shown in the work of Misawa

As shown in the accompanying table, there was a decrease of approximately 50 per cent in the chlorine

Chlorine Content in Grams per Gram of Tissue

Tissue	Normal	Water Intoxication	Per Cent
Brain	0.0519	0.0255	50.8 decrease
Liver	0.0165	0.0407	147.0 increase
Kidney	0.0356	0.0335	39.8 decrease
Muscle	0.0120	0.0435	40.3 decrease
Heart	0.0339	0.0313	4.8 decrease

content of the brain and a decrease of about 40 per cent in kidney and muscle, with the heart showing only a 5 per cent decrease In the liver an increase of approximately 147 per cent was observed

Fig. 13—Oil immersion photomicrograph of blood vessel of cortex in a rabbit's brain showing false space peripheral to outer lining of Virchow Robin space traversed by glial fibrils The brain tissue shows definite vacuolization

COMMENT

A number of theories have been advanced to explain the pathogenesis of the so-called water intoxication Thus, Smith and his associates⁷ believe that the symptoms of water intoxication are associated with the loss of chlorides and alkalosis Rowntree, on the other hand, as the result of both chemical and pathologic studies believed that the excessive absorption of water

6 Misawa H Ueber das Wesen der sogenannten Wasserintoxikation Jap J M Sc Tr VIII Int Med Pediat Psychiat 1:355 (Dec) 1927
7 Smith, F S Deamer W C and Phatak N M Studies in So-Called Water Intoxication J Clin Investigation 12 55 (Jan) 1931

produced an upset in the salt-water balance of the body with a resulting cerebral edema which was the direct cause of the clinical manifestations. In our experimental studies, the carbon dioxide combining power of the blood plasma was never increased and was usually decreased. The gross and microscopic studies of the brains both of our human case and of our experimental animals seem strongly to support the hypothesis advanced by Rowntree.

Explanation of the exact mechanism of water intoxication presents many interesting and complicated problems. It is difficult to account for the apparent susceptibility of the liver and brain for retaining fluid when tap water is given by bowel. It would appear that water intoxication was dependent on water elimination. The reason the kidneys fail to eliminate properly is unknown. In this respect, the experiments of Meier⁸ are interesting. He destroyed the brains of frogs and devised two circulatory systems, one included the heart, liver and kidneys, and the other included only the heart and kidneys. He observed that a certain rate of excretion was present when a perfusing fluid was run through the heart-kidney system, but a very definite increase in the kidney output took place at once when the liver was included in the "hookup." Similarly, Mann⁹ frequently noted anuria following complete extirpation of the liver. It seems, therefore, possible that some hepatic dysfunction may be of importance in the pathogenesis of water intoxication. It is interesting in this regard that biopsy of the liver of our patient at the time of operation showed a very advanced parenchymatous degeneration. Moreover, in the livers of all our experimental animals varying degrees of cloudy swelling were uniformly present. In this regard, it is likewise interesting that it has been impossible to produce an intoxication when hypotonic salt solution was administered or when 10 per cent chloride was given prior to the administration of water.

One may speculate as to whether an upset in the normal salt-water balance produces water intoxication or whether a lack of chlorides interferes in some way with the apparent relationship of the liver to renal output.

The mechanism of the acute cerebral edema is very puzzling. The most striking characteristic of the edema was its interstitial character and the fact that at necropsy there was no evidence of increased production of cerebrospinal fluid. On the contrary, the ventricles were decreased in caliber and there was scarcely any cerebrospinal fluid present, while apparently paradoxically there was histologic evidence of definite hyperactivity of the choroid plexus. Recently Terplan¹⁰ has recorded a case of death from insulin shock in which acute swelling of the brain was present. Grossly, the brain in his case closely resembled that observed in our case. He¹¹ attributes the cerebral edema to a hypotonic condition of the blood due to a marked diminution in blood sugar. Similarly, we might suggest the same mechanism for our results as that due to a decrease in blood chlorides. In addition, Ferraro,¹² by the administration of distilled water intravenously

has produced morphologic changes in the brain and choroid plexus quite similar to those observed in our studies. These facts strongly suggest that perhaps the most important factor in the production of the cerebral edema, which is the major pathologic lesion of water intoxication, is a disturbance in the normal isotonicity of the blood.

CONCLUSIONS

1 The possibility of producing water intoxication is emphasized as constituting one of the dangers incident to the injudicious forcing of fluids.

2 In a fatal case of apparent water intoxication, the patient, following a simple cholecystectomy, absorbed 9 liters of tap water proctoclysis within a period of thirty hours after operation and died in convulsions.

Fig 14—Oil immersion photomicrograph of rabbit's liver. Note marked sinusoidal dilatation and pale hemolyzing red blood cells in the sinusoids.

The most striking finding at necropsy was an acute swelling of the brain.

3 Young rabbits were given tap water proctoclysis, and the clinical and pathologic picture observed in the fatal human case was reduplicated in every instance in a series of seven animals. Chemical studies of the blood and tissues of these animals were carried out with interesting results.

Forty-Fourth Street and Mill Creek Parkway

New Fool-Proof Explosive—A revolutionary new blasting material for use in quarries and in other blasting operations such as stripping, was announced at the Eighteenth Annual Technical Section Convention of the Explosives Department of the du Pont Company which opened January 22 at Wilmington, Del. This new product it was stated cannot be detonated by the strongest commercial blasting cap by impact, by flame, nor by shooting a rifle bullet into it. In actual use it is exploded by means of a large diameter cartridge of dynamite. It is non-headache producing and is rendered absolutely water resistant by being sealed up tightly in a tin can. It is said to represent the ultimate in safety in so far as a blasting agent is concerned. This new development has been covered by two patents one for the product itself, which will be known as Nitramon, and the other covering its method of use. It is nonfreezing. This new product will be marketed only in large diameters—4-, 4.51 5- and 7-inch.—*Indust & Engin Chem* 27 93 (March 10) 1935

ROENTGEN RADIATION NECROSIS OF
LARYNX AND OTHER STRUCTURES OF THE NECK

PETER A. NELSON, M.D.

AND

EDWIN F. HIRSCH, M.D.

CHICAGO

According to Hahn,¹ when irradiation in 1910-1912 replaced surgery in the treatment of tuberculosis of the neck many patients suffered roentgen injuries of the throat. Even after the radiation had been reduced to three fourths of the toxic skin dose, patients so treated after several weeks, became hoarse. Because these patients had no skin reaction, their hoarseness was not associated with the radiation therapy. As the number of patients with hoarseness increased and examinations of the larynx demonstrated an obstinate edema which lasted several weeks radiation was recognized as the etiologic agent. The only reference to irradiation injury of the throat at that time, according to Hahn, was by Mühlmann, who had often noted a stubborn hoarseness in irradiated patients and, in two, a chronic laryngitis. Other reports of severe damage to the larynx and tissues of the neck by radiation were published in 1921 by Wetzel,² Holfelder,³ Schmidt,⁴ and Marschuk,⁵ and more in 1922 and 1923 by von Hofmeister,⁶ Feuchtinger,⁷ König,⁸ Mühlmann and Meyer,⁹ Van Rossem,¹⁰ and Jüngling.¹¹ The injurious effects of radiation on the larynx were so well known then that Jüngling described them as of three types: (1) an immediate reaction occurring within from one to three days, (2) a true roentgen reaction appearing from ten to twenty days after irradiation, and (3) a late reaction appearing any time after from four weeks to a year. In the first he stated, there is a moderate swelling of the neck especially of the subcutaneous fat and of the lymph nodes. The mucosa of the mouth has no appreciable edema, but sometimes a marked salivation is annoying. The true roentgen reaction is characterized by dryness of the throat, by hoarseness, and sometimes by edema and fibrinous exudates on the mucosa. The manifestations of the serious or late stage are edema, marked atrophy and scar tissue replacement of the structures in the neck, perichondritis and necrosis of the larynx. All the late stages may occur, according to Jüngling without any indications of an immediate reaction. Since the report by Jüngling, others on radiation injury to the larynx have been published by Schmitz,¹² Halberstaedter,¹³ Strandberg,¹⁴ Güssow,¹⁵ von der Hutten,¹⁶ Tonndorf,¹⁷ Thost,¹⁸ Iglauer,¹⁹ and

Posey.²⁰ Only the last two of these appeared in American Medical publications.

The amount of radiation therapy received by individual patients has varied. In some the quantity, admittedly was excessive, in others it was considered small, and in the remainder it was average, not known, or only approximated. Iglauer and others reporting these injuries have emphasized the danger of producing serious damage to the larynx by therapeutic irradiation of the neck and have advised careful protection of this structure against excessive or cumulative dosage.

Among the thirty-two instances of irradiation injury to the larynx recorded in the publications listed, by far the greatest number of deaths has resulted from the so-called late manifestations. Death, however, has been reported in both the other stages. The patient whose clinical record was reviewed by Schmitz died from the asphyxia of an immediate reaction, and one of the two reported on by Posey was saved from an acute death by tracheotomy. An analysis of the diseases mentioned for which radiation therapy of the neck was prescribed discloses a wide variety of actual or alleged disorders. Carcinoma of the larynx (nine) is the most frequent, then lymphoma of the neck (five), Trichophyton infections of the skin (four), papilloma of the larynx (four), tuberculosis of the cervical lymph nodes (three), Hodgkin's disease (one), exophthalmic goiter (one), keloid of the neck (one), actinomycosis (one), malignant tumor of the thyroid (one), a swelling of the base of the tongue and enlarged lymph nodes, considered malignant without tissue examination, and, finally, an acute laryngitis.

Radiation treatment of carcinoma, at present, is in a phase in which high voltage-low resistance doses are given. A warning may be in order at this time of the dangers of damage to the larynx by irradiation for carcinoma or other diseases and of the seriousness such injuries are to the patient.

A recent experience in which death followed severe late radiation necrosis of the larynx prompts this report.

REPORT OF CASE

An unmarried white man aged 26, consulted a physician in April 1933 because of an enlarged right upper cervical lymph node. This node was about 3.5 cm long and 2.5 cm wide. Without histologic examination of tissues and believing that the enlargement might be due to sarcoma the physician gave four courses of radiation therapy (skin dosage) during the following year spaced at intervals of two months. The node at first decreased in size but never disappeared entirely. March 27, 1934 an examination of the patient who then complained of difficulty in swallowing disclosed an inflammation of the right pillar and tonsil, and marked swelling of the tongue. He came into the care of one of us (P. A. N.) at Mercy Hospital where another examination March 30, demonstrated a hard movable, encapsulated mass 3 cm in diameter in the right submaxillary region and another, freely movable 1 cm in diameter in the left submaxillary region. There was a marked edema of the tongue and floor of the mouth, the tonsils had been removed. A nodule 2 cm in diameter was in the right lower tonsillar pillar and from this, tissues were taken for histologic examination. There was no ulceration of the mouth. The general physical and indirect laryngoscopic examinations disclosed nothing unusual. The clinical diagnosis was bilateral metastatic carcinoma of the cervical lymph nodes, secondary to a primary growth in the right tonsillar pillar. The tissues removed from this pillar and examined microscopically, however, contained normal tonsil tissues. The large right submaxillary lymph node was excised, April 6, and histologically it had only inflammatory changes and some edema. The submaxillary salivary gland tissues included with the lymph node

had also a marked fibrous tissue replacement but no tumor tissues. From March 30 to April 24, twenty radiation treatments were given on alternate sides of the neck with 800 kilo volts of roentgen rays. The roentgens at the surface of the field for each of the first twelve treatments were 308, for each of the next seven treatments 450, and for the last one 231. The immediate reactions from the irradiation were severe, as occurs in all patients subjected to this method of treatment. The radiation fields extended from the clavicle upward. The adja-

Fig. 1—Marked necrosis of the lining of the larynx. The necrotic and displaced cricoid cartilage is just above the tracheotomy opening.

cent body surfaces were protected with heavy lead rubber and 0.5 cm of lead. The patient, however, seemed to remain in good condition except for dryness of the throat and some edema of the arytenoids. May 16 after the radiation therapy had been completed, a severe reaction developed on the inside and outside of the neck.

There is here a gap in the clinical history of the patient until September 10, about which time he was admitted to the Edward Sanatorium. At that time he was silent because of a severe laryngitis thought to be tuberculous. The observations made there are not known to us. He entered St. Luke's Hospital October 2 in the service of Dr. E. P. Norcross unable to speak above a whisper. He had had difficulty in swallowing and a sore throat for three months and cough and pain in the right ear for one week. He could drink only with difficulty and could scarcely swallow even soft foods. Dr. Norcross during his examination, October 3, noted that the skin of the neck seemed to have been burned recently by some form of irradiation and that the base of the tongue was indurated especially the right side. The anterior surface of the epiglottis, both valleculae, the hypopharynx and the arytenoids were edematous. Both vocal cords were thin and their excursion was limited. Thick mucus filled both pyriform sinuses. October 6 the vocal cords were closely approximated and because of the marked dyspnea the larynx was intubated. The dyspnea and other symptoms became worse so that on October 10 a tracheotomy was performed. In spite of this and supportive measures the patient's dyspnea continued; the temperature ranged daily between 101 and 103 F and he died October 29 at 12:30 p.m.

The essentials of the anatomic diagnosis of the postmortem record are marked gangrenous ulceration (radiation necrosis)

of the pharynx, larynx and upper parts of the trachea and esophagus, sequestration of the cricoid cartilage, marked brawny induration and atrophy of the tissues of the neck, recent surgical tracheotomy wound of the neck, necrosis and acute cellulitis of the tissues about the tracheotomy wound, acute cellulitis of the tissues of the mediastinum, acute bilateral bronchopneumonia of the lungs, acute hyperplasia of the tracheobronchial lymph nodes, cloudy swelling of the myocardium, liver and kidneys, and bilateral fibrous pleuritis.

The markedly emaciated body was 158 cm long and weighed 87 pounds (39.5 Kg). The mucous membranes of the front of the mouth were pale and the cervical lymph nodes were not enlarged. An oval tracheotomy wound of the neck was 4 cm long, 2.5 cm wide and extended cone shaped 3 cm into the lumen of the trachea. The walls were necrotic and brown-black. Dense fibrous adhesions bound each lung to the chest. The pleural spaces contained no fluids. There was a marked brawny induration of the neck in front of the spine. The skeletal muscles were pale red and matted into indurated tissues about the trachea. The tissues in and about the tracheotomy wound including the cartilage rings were necrotic and had a foul odor. The lining of the trachea was ulcerated and necrotic to the level of the clavicle, and all the structures of the neck including the carotid sheaths were bound together. These tissues of the neck were removed in one mass (fig. 1) for examination. A perforation of the posterior wall of the trachea opposite the tracheotomy wound extended into the soft tissues about both carotid arteries but did not erode these vessels. The cellulitis had spread behind to the anterior longitudinal ligament of the spine and here was an abscess 3 cm in diameter, filled with purulent material. The vertebrae were not eroded. The brawny induration and necrosis of the tissues extended upward on both sides of the neck to the

Fig. 2—Necrotic tissues lining the larynx and in the deeper portions cartilage also necrotic. $\times 76$

mandible. The entire wall of the larynx was necrotic and several pieces of cartilage including the entire cricoid cartilage were held loosely in the necrotic soft tissues. The destruction of the internal surfaces of the larynx was so marked that the vocal cords and other structures were no longer present. The upper part of the esophagus also was markedly ulcerated, hyperemic and edematous down to the level of the clavicle but mainly above and behind the larynx where the wall had several perforations. The epiglottis was slightly eroded, edematous and hyperemic. In the pharynx the necrosis extended to the

level of the faucial tissues. A small amount of lymphoid tissue was in each tonsillar fossa. The thyroid gland was embedded in indurated fibrous tissues. On surfaces made by cutting it was gray-brown, dry tissue. The cervical lymph nodes on both sides were about 1.5 cm in diameter. They were moderately firm and on surfaces made by cutting had the usual gray lymphoid tissue.

Histologic examinations were made of tissues cut from the margin of a transverse bisection of the larynx so as to include portions from the entire circumference. The lining tissues in these places were markedly edematous, necrotic, fibrillar mucosa without exudates or nuclear structures, simply a stroma framework of devitalized tissues (fig. 2). Even the thyroid cartilage tissues were necrotic. The tissues bordering the necrotic portions had a markedly edematous hyaline stroma with a few shrunken nuclei. The structure of these tissues resembled that of tissues elsewhere in the body injured by radiation therapy.²¹

COMMENT

The radiation therapy given this patient, while admittedly large and obviously excessive for his tissues, was according to the procedures of the present trend in roentgen therapy, namely, the use of large quantities of high voltage-low resistance rays. The unfortunate result, however, should be attributed to the combination of four series of low voltage roentgen rays and one series of 800 kilovolts of roentgen rays. The dosage of the latter given has not been followed by such destruction reactions. The experience here related is again a warning that roentgenologists should safeguard their patients against radiation injuries, especially when sensitive tissues such as those of the neck are treated.

UNILATERAL SUBLUXATIONS OF THE CERVICAL VERTEBRAE WITHOUT ASSOCIATED FRACTURE

BARBARA B. STIMSON, M.D.

AND

PAUL C. SWENSON, M.D.

NEW YORK

Since Jan. 1, 1929, there have been sixty-six cases of unilateral subluxation of the cervical vertebrae without associated fracture seen in the fracture service of the Presbyterian Hospital. Of these, five were seen in the first three years and thirty-nine in the past eighteen months. This sudden and spectacular increase is due not to any change in the neck structure of New York's population but to the education of the members of the staff in the recognition of the condition. We feel, therefore, that it is of value to present this group of cases not in order to describe a new condition or method of treatment but to refresh the memory of the profession at large as to the characteristic picture these patients present and to set forth our experience in their treatment.

Of the sixty-six patients, thirty-six were male and thirty female. Fifty-two were between the ages of 10 and 29 years, the youngest of the series being 6 and the oldest 60.

Fifty-two patients came for treatment within twenty-four hours of the onset of symptoms, ten more within a week. One woman came into the clinic a year and a half after her original trauma, still suffering from pain, disability and deformity.

The initiating trauma is apt to be very slight but to occur when the muscles are "off guard," as for example when the patient has just awakened. A sudden lurch on stretching in bed, a turn in answer to a call, a jerk of the head to catch a forward pass, a twist in taking off a dress over the head have all been cited as the cause for the symptoms from which the patient sought relief. Two of the series received their injuries in motor accidents and two in diving.

Following such a sudden twist as one of those just described the patient feels sudden pain and finds that he cannot straighten his head. The pain usually subsides quickly, only to recur when motions of the neck are forced, but it and the disability are usually sufficiently definite to force the patient to seek medical attention fairly soon. He often volunteers the fact that it does not feel just like a stiff neck.

The picture the patient presents is characteristic. The head is tipped and tilted to one side and is moved with great care. Voluntary flexion and extension of the neck are usually possible and rotation and further tilting on the side toward which the head is already inclined can be done easily and painlessly. But the head cannot be inclined toward the opposite side. Passive motions bring out the same manifestations. In other words, if the head is tilted to the right the right ear can be brought down toward the right shoulder, but on attempting to bring the left ear to the left shoulder a definite resistance is encountered and the patient usually complains of pain. Rotation to the affected side may or may not be impaired, but lateral flexion is invariably resisted. Muscle spasm is usually present and is found on the "long" or affected side in contrast to torticollis, in which the spasm is on the "short" side toward which the head is bent. There is usually tenderness over the affected vertebra on the "long" side. Three patients complained of pain radiating down the shoulder and arm. No other signs or symptoms of cord or nerve root involvement were noted.

The differential diagnosis has been of considerable interest to us, as we have encountered two schools of thought among our colleagues: one of complete skepticism as to the existence or at least importance of a cervical subluxation and the other of such complete acceptance that they believe that any one with a pain in the neck must have, *ipso facto*, a partial dislocation. It has been necessary to answer the objections of the former and to sift out the wheat from the chaff in the cases referred to us by the latter.

Various lesions may be mistaken for a true subluxation. Of these, the most common is acute myositis of the trapezius. This can be distinguished by the absence of the block to lateral flexion although motions may be painful, and by the tenderness in the muscle belly, not localized over the vertebra as in subluxation. Cervical adenitis may cause a tilt of the head and limitation of motion, but careful palpation will reveal the tender glands, and motions will be possible though painful and limited in extent. Arthritis of the cervical spine will cause a generalized limitation of motion, not especially lateral flexion to one side. Torticollis will have the muscle spasm on the "short" side toward which the head is bent, and if there is tenderness it is over the spastic muscle on the "short" side.

The conclusive proof of the diagnosis of subluxation, however, lies in the stereo lateral roentgenograms, which will show the sliding forward of one articular facet on the one beneath it.

21 Elliott A. R. and Jenkinson E. L. Radiology 23: 149 (Aug.) 1934.

From the Department of Surgery, Columbia University College of Physicians and Surgeons and the Fracture and Roentgenological Service, Presbyterian Hospital.

Our routine films include stereoscopic roentgenograms in both lateral and anteroposterior projections, also an anteroposterior projection through the open mouth to delineate better the first two segments, particularly the odontoid process. We would emphasize that stereoscopic films are essential in order that the finer variations from the normal may be recognized. Even in the most marked cases the lateral projections are difficult to interpret unless the third dimension is appreciated which 'separates' the various structures that are otherwise superimposed.

In the usual case the facet surface of one segment is seen displaced upward and forward on that of the corresponding one below. There is usually an associated slight backward displacement of the corresponding facet on the other side, owing to the rotary nature of the displacement. This is recognized best in the lateral view (figs 1 and 2), although the anteroposterior view will give one the impression of a longer superimposed facet shadow on the side of the displacement. Moreover, one will see the tilt of the spine and chin to the opposite side.

The objection has been raised that if the lateral projections are slightly oblique one will get a false impression of subluxation, but if one is careful to use the anterior margins of the facet surfaces as an index of the amount of displacement this source of error can be disregarded. We have satisfied ourselves that the roentgen picture produced by the clinical entity we describe cannot be reproduced by the attempt of a normal individual to assume an attitude corresponding to that seen in a clear cut case of subluxation.

Among the sixty-six cases we have not seen any that has shown a complete forward displacement with the facet slipped forward into the intervertebral notch. In only one case was the roentgen study negative. This

Fig 1—A representative film showing subluxation of the articular facet of the third segment on that of the fourth

can be expected in an occasional case, since very slight displacements may take place which may have been reduced spontaneously or with only slight manipulation. It is necessary when placing the patient for roentgenography. The symptoms of pain and spasm persist for a time in spite of the reduction.

In thirty-seven cases the subluxations occurred between the second and third cervical vertebrae, none between the first and second and one at the sixth and seventh. The others were fairly evenly divided between the remaining levels.

We have modified our treatment somewhat since our first article was written. Of the last thirty-nine cases, seventeen were treated by simple head traction of from 5 to 15 pounds, depending on the size of the patient and lasting from twenty-four to seventy-two hours. Two subluxations were not reduced by this method and required manipulation under general anesthesia. Seventeen patients were treated in a manner described by Dr. Stookey¹ for more severe fracture-dislocations.

Fig 2—Same case as in figure 1, lateral film (after reduction)

on an air mattress in which hyperextension of the neck is obtained by allowing the head to lie in a trough made by compressing the mattress with a wide strip of adhesive plaster. Three of the results were unsuccessful and the dislocations were reduced by head traction. Two cases were successfully manipulated as primary procedures and three reduced spontaneously either on the X-ray table or during the process of examination.

No form of immobilization was used on the three cases that reduced spontaneously. In the group in which reduction occurred very quickly after admission to the hospital and which seemed to be of a mild type, a Schanz collar of cotton and muslin was applied and maintained for from ten to fourteen days. Patients who required more strenuous efforts for reduction who had had recurrences or who had marked symptoms were immobilized in plaster collars for four weeks.

Five of the sixty-six cases have recurred: one at seven days in an active small boy who twisted inside a loosely fitting collar, one at twelve days in a girl who removed her plaster collar against advice to go to a dance and subluxated it at the dance, one at six weeks in a patient who had cut down his plaster collar a week after leaving the hospital, one at seven weeks in a woman who had worn a plaster collar for four weeks and one at five and one-half months in a man who had worn a plaster collar for four weeks.

CONCLUSION

We would stress again the composite picture presented by the sixty-six cases here reviewed: a relatively young adult who seeks relief for stiffness and pain in the neck within twenty-four hours after a mild twist or jerk of the head and who holds his head tilted to one side and cannot bend it to the opposite side. Adequate roentgenograms are necessary for conclusive diagnosis. Treatment is relatively simple after the diagnosis has been established.

BACK STRAIN AND SCIATICA

FRANK R. OBER, MD
BOSTON

SCIATICA—OBER

JOUR. A. M. A.
MAY 4, 1935

It is my purpose in this paper to present a new theory relating to the cause of lame backs. The members of the profession at large know only too well that there are many symptoms of low back disabilities for which there have been no explanations. The terms sacro-iliac strain and dislocation or lumbosacral strain are in common use. Up to the present, these explanations have satisfied most physicians, depending on which side of the fence they happen to be. When roentgenograms of the sacro-iliac and lumbosacral joints are presented which show no evidence in this region of any pathologic condition, either congenital or acquired, it would seem difficult to make a positive diagnosis of either sacro-iliac or lumbosacral strain. One is frequently troubled by the fact that there is a negative roentgenogram of a patient whose clinical signs and symptoms are those of extreme irritation in the sacro-iliac or lumbosacral joints. As a result of observation and examination of a number of cases of this type it has been discovered that the ilio-tibial band is an exceedingly important factor in the occurrence of lame backs, with or without an associated sciatica.

ANATOMY

The fascia lata is a sheath that surrounds the thigh muscles, with trabeculations that pass between the muscles and form intramuscular septums. This fascia is controlled by a muscle known as the tensor fasciae latae which is attached to the crest of the ilium at its anterior and lateral aspects. It extends down below the trochanter, ending in the iliotibial band. The whole iliotibial band extends from the crest of the ilium down the lateral aspect of the leg and is inserted into the outer tuberosity of the tibia and forms in its lower three quarters the tendon of the tensor. The maximus muscle is inserted into the posterolateral aspect of the femur below the base of the greater trochanter, and in this region there is a widespread aponeurotic connection between the gluteus maximus tendon and the posterior part of the iliotibial band (fig 1).

Fig 1—Anatomy of the iliotibial band (Sobotta and McMurrich Anatomy)

PATHOLOGY

It has been observed in many patients with low back disturbances that the iliotibial band is extremely tight and prominent when the patient is lying on his back, with the knees together or when he is in the erect position. The band is very rigid almost bone-like in consistency, when under tension usually about one-half inch wide, and is raised above the level of the fascia lata, with which it connects anteriorly and posteriorly

It is easily located in a line, usually just in front of the trochanter. It may be situated immediately over the trochanter or it may be a little posterior. When the band is situated immediately over the trochanter, many patients complain of a snapping sensation in the hip. This snapping sensation is due to the riding of the band back and forth over the trochanter. Many writers have been cognizant for a long time that this is the cause of snapping hips. When the contracture is present on one

Fig 2—Method of showing abduction contracture.

side, a lateral deviation of the spine is produced on that side and the pelvis is found to be tilted. The mechanics of the contracture and the leverage produced by the contracture are so great that it is possible that the unilateral contracture may account for irritation in the sacro-iliac joint. When both bands are tight and in front of the trochanter, the lumbar spine is held in lordosis in both the standing and recumbent positions. If contracture is posterior to the trochanter, the spine is held in a lumbar kyphosis. In two of the cases to be reported in which operation was done, a chronic, inflammatory condition was found in the iliotibial band under microscopic examination. In one case there was a report of perivascular cellular infiltration in the intermuscular connective tissue and a loss of cross striations in the muscles.

SYMPTOMS

Patients who have this contracture complain of the low back pain as a sensation of strain in the low part of the back in the region of the lumbar and sacral bones or in the sacro-iliac articulations. Severe sciatica is associated quite often with the condition and there also may be pain along the lateral femoral cutaneous nerve and occasionally along the distribution of the femoral nerve. Those who have the double contracture may show sciatic irritation on one side or both sides, or alternating attacks.

EXAMINATION

- 1 Straight leg raising is usually limited whether sciatica is present or not.
- 2 When these patients are asked to sit down and bend the body forward, with the legs extended on the examining table, it is very rare for the lumbar spine and pelvis to flex even to a right angle (fig 3). Many of these patients are unable to stoop over and touch the floor with their hands (fig 4).
- 3 In most cases, Ely's sign is present. (This sign was first described as pathognomonic of sacro-iliac irritation or disease.) As a matter of fact, Ely's sign merely indicates a contracture of the fascia lata. This sign is obtained while the patient is lying prone on

the examining table. The examiner flexes the leg on the thigh and as the flexion takes place the pelvis rises from the table.

4 The most important diagnostic sign of the contracture is obtained as follows. The patient is placed directly on his side. The examiner places one hand on the pelvis to steady it and grasps the patient's ankle lightly with the other hand holding the knee flexed at a right angle. The thigh is abducted and extended in the coronal plane of the body (fig 2). If the contracture described is present the leg will remain abducted, the degree of abduction depending on the amount of contracture present. This sign is present both in the conscious and in the anesthetized patient. If there is no contracture present, the thigh will adduct beyond the median line.

TREATMENT

The treatment of this condition resolves itself into one factor, and that is the relief of the contracture. In those cases in which there is no sciatica or other pain, the low back pain may be relieved by stretching exercises carried out in the following manner:

The patient stands with the affected side about $2\frac{1}{2}$ feet away from a table or some other convenient object which he grasps with one hand then with his shoulder and pelvis in the same plane he bends the affected hip toward the table as far as he can his whole figure forming an arc. This position is maintained for a few seconds and then repeated five times the first day and is increased once each day until the exercise is done twenty-five times, twice a day.

In those cases in which there is a severe sciatica, operation is indicated and the method of procedure is as follows:

1 An incision is made from just below the crest of the ilium down to the tip of the trochanter, directly over the contracted iliotibial band.

Fig 3—Illustrating shortening of the posterior muscles sitting

2 The fascia lata is exposed forward as far as the anterior superior spine and backward to the edge of the gluteus maximus muscle. The area of the greatest contracture of the fascia can be seen readily and felt easily.

3 The fascia is now divided transversely from just below the anterior superior spine to the anterior border of the gluteus maximus muscle (fig 5). There is immediate separation of the cut edges for a distance of from $\frac{3}{4}$ to $1\frac{1}{2}$ inches depending on the amount of contracture present. If the operator now attempts to carry out the test described it will be shown that the thigh will completely adduct.

Several patients with low back symptoms and severe sciatica have been operated on, some of them with

almost dramatic results. These patients have suffered from severe sciatica, lasting, in many instances, for several months. In cases 1 and 3 the relief from sciatic pain was almost immediate, there being a marked diminution of symptoms within twenty-four hours following operation. In several of the other cases the sciatic pain persisted for about six weeks and in one case lasted for eight weeks after operation, the sciatica subsiding very slowly. Thirteen patients have been operated on with relief in all instances except one.

Before the surgeon does this operation he should be very sure that there is no pathologic condition in the spinal canal, especially in the region of the cauda equina. The explanation of the amelioration of the sciatic symptoms and the low back disability

might possibly be made on two grounds. First, that the shortness of the iliotibial band and the contracture of the fascia lata causes a squeezing effect on the sciatic nerve where it passes over the acetabulum. Second, an explanation which seems to be more reasonable, that the mechanical pull of the contracted bands or band is producing a mechanical strain of the sacro-iliac or lumbosacral articulation.

Fig 4—Illustrating shortening of the posterior muscles, standing. Contracture of the iliotibial band plays a large part in this condition.

REPORT OF CASES

CASE 1—A F, a man aged 39, seen Feb 5, 1934 complained that while leaning over to dry his left foot following a bath and resting the left foot on the tub bearing his weight on the right foot, he felt a sudden tearing pain in the right lumbar regions. There was no radiation of the pain. There was slight local tenderness to the right of the lumbar spine.

The patient had been leading an active life playing squash regularly until 1932 when he had an attack of angioneurotic edema of the meninges and had no physical exercise until July 1933. In October 1933, following a game of squash he awoke the next morning with severe pain in the right lumbar region which persisted about four weeks. There was no radiation of the pain and only slight local tenderness. Four weeks later he had another attack after playing squash for a few minutes. In the next four weeks the pain grew steadily more severe. It was aggravated by walking standing and sitting and from time to time there was a dull radiation of pain toward the right ischial tuberosity. Coughing and sneezing increased the pain.

Examination at this time showed the ankle jerks equal and active and no tenderness over trunk or nerve. Passive flexion of the hip with the knee extended was painful and the pain was referred to the thigh, buttock and right ilio-lumbar angle. A belt gave no relief.

In January 1934 the pain was increased and was constantly present as a severe ache in the gluteal region. The patient had severe cramplike pains radiating to the posterolateral aspect of the thigh and outer aspect of the calf and foot. Pain was aggravated by walking and standing. At this time he was taking from 4 to 5 grains (0.2 to 0.3 Gm) of codeine and

from 40 to 50 grains (2.6 to 3.2 Gm) of acetylsalicylic acid daily. February 5 a tailored corset was applied, which gave some relief, so that the patient was able to walk with less discomfort, but the sciatic pain was almost unbearable if he attempted to stand a few minutes without the support.

February 17 he had an attack of influenza and was confined to bed, with almost immediate exacerbation of the pain. When he entered the hospital there was some decrease in the right ankle and knee jerks and slight diminution in all forms of superficial sensation along the distribution of the sciatic nerve. The general physical examination was negative. No foci of infection could be found. Roentgen evidence of the disturbance at the fourth lumbar vertebra on the left and complete sacralization of the fifth lumbar vertebra on the right and it was incomplete on the right. Diathermy and heat gave no relief. Epidural injections consisting of 0.5 per cent procaine hydrochloride and physiologic solution of sodium chloride to a total volume of 280 cc, were given with moderate relief. Massage given in March was painful. The patient remained in bed most of the time from February 17 to April 30.

Examination showed limitation of motion of the lumbar spine in all directions attended by marked spasm of the lum-

Fig 5—Separation of the iliotibial band after section

bar muscles. Very few degrees of forward flexion were allowed. Straight leg raising was markedly limited on the right and not on the left. The iliotibial band on the left side was moderately contracted. On the right side it was contracted so that there was about 10 or 15 degrees of permanent abduction.

May 2 under a local anesthetic the iliotibial band was divided as described. The patient was returned to bed after his breakdown and suffered some local discomfort as a result of the operation. At 5 p.m. he walked unassisted to the bathroom. When he stood without support, pain radiated to the old area, especially outside of the calf, but the intensity and quantity were diminished. May 3 he stood up and gave himself a sponge bath and shaved. He had been unable to stand this long without support for three months. There was a moderate amount of pain in the outer calf. A pathologic specimen removed at the time of operation showed degeneration of the fibrous connective tissue.

The patient left the hospital May 5 and flew to New York. No supporting belt has been worn since May 8. The only discomfort that he has had is a transitory sensation in the region of the incision. May 24 he walked 4 miles two of them without resting and the only effect of this was moderate fatigue. From the patient's point of view the most striking factor has been the dramatically striking change in the character of the pain. It was almost unbearable in the beginning and now it

has entirely disappeared. The patient was an excellent one from the surgeon's standpoint, as he is himself a neurologist.

CASE 2—A D, a woman, aged 31, married the wife of a physician, seen June 13, 1934, had for a number of years had pain in the lower part of the back, which was worse after prolonged standing, and occasionally it was troublesome in clearing up. Previous to June 13, 1934, she had been admitted to the Lakeside Hospital on two different occasions with severe sciatica. On one occasion the left sciatic nerve was stretched and on another saline injection was performed. The present attack began about six months before and was limited to the course of the left sciatic nerve. The patient was forced to go to bed for four months before admission on account of the severity of the pain. It was severe when she was sitting or bending the body. Roentgenograms had been entirely negative. Baking and massage gave no relief.

The patient was well developed and nourished and did not appear to be acutely or chronically ill. She was uncomfortable on moving and complained of constant pain in the posterior part of the left leg. There was tenderness along the course of the left sciatic nerve and in the region of the ischial tuberosity well down below the knee. Sensation everywhere was normal. The achilles jerk was absent.

June 13 I performed an operation on the left iliotibial band, dividing the band through the usual incision. Following the operation there was some relief from the sciatic pain. There was some discomfort in the wound and some pain low down at the anterior surface of the thigh. She was discharged from the hospital on the fourth day with marked improvement in the sciatica. There was complete disappearance of the sciatica in six weeks and the patient resumed a normal life on the eighth week with no pain.

CASE 3—J A, a Negro man aged 26, single, seen June 13, 1934, had first been seen by Dr. E. B. Castle of Cleveland, April 25, 1934, with a history of sciatica of six weeks duration. He had slipped and fallen down stairs, twisting his body when attempting to save himself.

Examination on his first visit showed considerable spasm of both erector spinae groups of muscles. Most of his complaints referred to the left sacro-iliac joint. There were some left sciatic symptoms with pain radiating down the posterior aspect of the thigh. The left side of the pelvis tilted and there was a compensatory scoliosis. Straight leg raising on both sides caused pain in the region of the left sacro-iliac joint. The usual treatment was carried out. The back was strapped. He was given large doses of sodium salicylate, and heat was applied. There was no improvement.

The patient was seen in consultation with Drs. Maxwell Harbin and E. B. Castle. June 14, under gas-oxygen anesthesia, a left iliotibial fasciotomy was carried out through a transverse incision midway between the greater trochanter and the iliac crest. The second day after operation the patient sat on the edge of the bed and had no pain in the back and the spine was straight. At the time of operation the patient had a marked scoliosis and during the six weeks previous treatment it had grown steadily worse. The patient was discharged on the seventh day after operation. After he got out of bed a very small amount of the scoliosis returned but this disappeared promptly within a week. The patient returned to work, July 9, approximately three weeks after operation, fully recovered.

CASE 4—F K, a white woman, aged 33, married, seen July 16, 1934, complained of a lame back of twenty-one years' duration. She had been worse since the birth of a boy ten years before. She had been in constant pain and more or less uncomfortable with attacks of sciatica down the right leg. One year before she had a bad attack and was confined to bed from November to July. For six weeks she had been very uncomfortable. During that time she was up once but had severe pain in the left leg going down to the heel and the side of the foot. Sometimes she had pain over the outer side of the thigh, which kept her awake. She was uncomfortable in any position except the semiprone position with the left thigh flexed.

Physical examination July 16 showed that when she was standing all motions of the spine were limited with moderate muscle spasm. Straight leg raising was markedly limited on

both sides but more on the left. There was marked shortening of the iliotibial bands, more marked on the left. Ankle jerks were diminished on the left. Other reflexes were normal. There was weakness in the dorsal flexion of the left foot.

On July 18, under general anesthesia, both iliotibial bands were divided. July 26, straight leg raising was possible to 50 degrees on the left side and 60 degrees on the right. The power of dorsal flexion had increased. She was taking no sedatives after having taken them for nearly a year. Pain was decreasing. By August 11 the conditions had improved markedly. She walked better, with less sciatica. There was no weakness in dorsal flexion of the foot. September 16 she still had a moderate amount of sciatica in the posterior aspect of the thigh, but none down the leg. The patient could put on shoes without difficulty, which she could not do before operation. Straight leg raising was 80 degrees on the left side and to a right angle on the right. There was still slight limitation of the back motions, with a list to the left. The patient felt better than she had for years.

A pathologic report of the specimen removed at the time of operation was acute and chronic inflammation. Muscle fibers showed loss of striations.

CASE 5—A T, a white woman, aged 37, married, seen July 17, 1933, had had a lame back since she was 20, radiating first down one leg and then the other. Pain in the back was very acute in May 1931. Sciatica on the left side was very severe and she was confined to bed part of the time. The condition was much worse throughout 1931 and no ankle jerks were present at that time. Since then she had had difficulty with moderate and mild attacks of sciatica. At the present examination she complained of sciatic pain down the right leg with tingling and numbness. The patient has had snapping hips all her life.

Examination showed poor posture, posterior kyphosis at the lumbosacral region, and rounded shoulders. The lateral motions of the spine were free. The patient on sitting with the legs extended and bending forward, felt pain down the right sciatic nerve. There was no muscle spasm. Straight leg raising was considerably limited on both sides. Reflexes were normal except for an absent ankle jerk on the left. There was contracture of both iliotibial bands.

July 8, 1934, another examination was made, the patient's sciatica on the right side had cleared up a few months before. She now had pain on the left side with hamstring spasm. It was impossible to extend the leg completely while sitting. She had pain in both legs at night.

August 26 both iliotibial bands were divided. On the fifth day she had relief from the discomfort. She was seen on September 20, and while left sided sciatica was still present it was not so severe. The patient was last seen October 22 and at that time the sciatica had entirely disappeared. Straight leg raising was about 75 degrees.

SUMMARY

- 1 The chronic lame back problem has not yet been solved.
 - 2 The contracted fascia lata is a common cause of lame backs and has been unrecognized.
 - 3 If this is so, it would seem, in the presence of normal roentgen studies, that fusion of the sacro-iliac or lumbosacral regions should not be done.
 - 4 When the fascia lata is contracted, it must produce bad posture.
 - 5 Therefore, apparatus designed to hold the abdomen or the back, or exercises given to straighten the back will be ineffectual against such severe contractures.
 - 6 The method of treatment proposed is so simple and so beneficial that it should have a place in the armamentarium of the surgeon.
 - 7 No attempt has been made in this article to discuss other known conditions that cause low back disabilities.

CUTANEOUS MANIFESTATIONS OF THE LYMPHOBLASTOMAS

REPORT OF A CASE OF HODGKIN'S DISEASE

ADOLPH B. LOVEMAN, M.D.
LOUISVILLE, KY

The general practitioner is often called on to diagnose and treat various types of skin disorders. Many of these are local conditions peculiarly confined to the skin, whereas others are definite cutaneous manifestations of some systemic disease. Some run a benign course, while others are expressions of a neoplastic process. Any discussion that will aid the physician in arriving at a diagnosis or arouse his suspicions that he is dealing with a cutaneous expression of some hidden visceropathy seems worth while. With this in view, a general discussion of the lymphoblastomas would seem to be of value.

In this discussion the term lymphoblastoma is used to designate certain diseases of the hematopoietic system. Those which often give rise to cutaneous manifestations are Hodgkin's disease, mycosis fungoides, the leukemias (both myeloid and lymphocytic) and

Fig. 1—Section of the lymph nodes showing numerous large vesicular cells and one giant cell.

lymphosarcoma. Occasionally these manifest themselves here before their demonstration in other parts of the body is possible.

It is not within the scope of this paper to discuss the various symptoms and cutaneous manifestations of these individual diseases. They have in common one cutaneous manifestation, however, which is so frequently observed that it deserves special emphasis. This is a generalized exfoliative dermatitis, or universal scaly erythroderma. Whenever such a condition is encountered and persists in spite of treatment, it should always be regarded as belonging to one of the malignant lymphadenoses until definitely ruled out.

Keim¹ has recently discussed the interrelationship of the various lymphoblastomas. He believes that this group of diseases presents itself under multiple clinical pictures and that the various clinical types encountered present interchangeable pathologic observations. He adds that the one constant pathologic condition in all

of these is a cell belonging to the lymphocytic series and, "until further information is forthcoming concerning distinct etiology, the term lymphoblastoma would seem to be justified on the basis of the genetic relationships existing between the members of this group"

All of these diseases are so closely interrelated and merge one into the other so often that one cannot pre-

dict that a typical case of cutaneous Hodgkin's disease might not present a leukemic blood picture before death. Cases of exfoliative dermatitis have been known to persist for months with no evidence other than the biopsy that the condition was lymphoblastoma. Occa-

Fig 3—Section under low power showing dense infiltrate in upper corium with some tendency of cells to arrange themselves in clumps

sionally these symptoms have been seen to disappear under roentgen therapy, the patient enjoys a remission for months and even years, only to return later with sufficient clinical evidence to permit then a specific diagnosis of leukemia, Hodgkin's disease or one of the other associated conditions. Transitions and mutations from one type to another have been reported by

numerous investigators, including Wile,² Kristjanson,³ Keim,¹ Montgomery,⁴ Wile and Stiles,⁵ Fraser⁶ and others. Ginsburg,⁷ in a comprehensive review of lymphosarcoma and Hodgkin's disease, concludes that these conditions are fundamentally and biologically similar. He believes that whatever variations exist at times "are merely variations that one would expect to find in any disease affecting different individuals under different constitutional and environmental conditions"

Wile and Stiles⁵ in a recent discussion of clinical mutations in lymphoblastomas, reported a case of eighteen years' duration originally diagnosed as the prefungoid stage of mycosis fungoides, which finally developed into a typical Hodgkin's disease, proved by biopsy. They believe that "clinical mutations that occur between various types of lymphoblastomas constitute strong evidence in favor of the view that lymphoblastomas are genetically related neoplasms involving the lymphoid tissue." A similar opinion from the pathologic point of view was expressed by the late Dr. A. S. Warthin⁸

Fig 4—Same as figure 3 under high power showing polymorphism of individual cells and variations in cell type

Although I am in accord with this view concerning the interrelationship of this group of diseases—as well as their neoplastic origin—one should be appreciative of the relationship of Hodgkin's disease to tuberculosis, as emphasized by L'Esperance⁹ Rulison¹⁰ and others. The former in addition to recovering the avian type of tubercle bacilli from certain cases, likewise developed an avian tuberculin used intradermally as a diagnostic aid. Steiner¹¹ found no evidence of specific sensitization to the avian tuberculin protein in his cases. He found a marked desensitization (absence of sensitiza-

tion) to both human and avian strains of tuberculin. He believes that Hodgkin's disease either desensitizes to these tuberculin proteins or else occurs only in persons in whom the normal sensitization to the tuberculin protein is impossible. He cannot conceive of either of these occurring without some relation to tuberculosis.

The greatest aid in the diagnosis of the lymphoblastomas is the early skin and lymph gland biopsy. The histology is quite characteristic—an infiltrate of lymphoblastic cells occurring in the upper portion of the corium either as a sharp, bandlike infiltrate or in clumps. The lymph gland biopsy will usually show marked hyperplasia and the same type of lymphoblastic cells as seen in the skin. Numerous cases have been so diagnosed from biopsy months and even years before there was other evidence clinically to substantiate a specific diagnosis. Just as there are mutations and interrelationships clinically in these diseases, so there are pathologically. Frequently the biopsy reveals only a nonspecific lymphoblastoma the specificity of which can be determined, if at all only by the clinical observations. Quite often the clinical and pathologic diagnoses differ with regard to the specificity of the lymphoblastomatous process. Many cases of cutaneous and hematogenous leukemia have been diagnosed Hodgkin's disease at postmortem by competent pathologists. McCartney¹² reported a case in which the microscopic studies of the lymph glands revealed four distinct histologic types. In some areas the pathology was typical of Hodgkin's disease with Dorothy Reed cells while other portions simulated lymphatic leukemia, primary endothelioma of lymph nodes, and lymphosarcoma. Such occurrences are not at all uncommon and perhaps explain the differences in pathologic diagnoses often obtained.

According to Wile,² the lymphoblastomas may manifest themselves cutaneously in three different ways. The first group are true metastatic lesions occurring in the presence of lymphadenotic blood pictures. These may express themselves cutaneously as tumors, infiltrations, hyperpigmentation or otherwise. In the second group the cutaneous expressions may antedate involvement of the blood and lymph glands. Most of the cases of exfoliative dermatitis fall in this group. The third group includes the scaly erythrodermas, localized tumors, and so on, in which transitory deviations from normal blood pictures are found as well as changes in the lymph glands. Wile believes that although the majority of the cases are lymphoblastomas at the onset there are perhaps a few cases in which the lymphadenosis is secondary to a prolonged skin insult. It is quite likely that the following case is such an example.

REPORT OF CASE

History.—A man aged 55, referred to me Aug. 22, 1933 by Dr. Harry S. Frazier had been confined to bed intermittently for the past year and continuously for the past few months. In September 1932 he got some rust remover on his hands and wrists and, before washing this off, had contaminated his penis and scrotum. The following day he noted itching of the hands, wrists and scrotum. He stated that these were red and inflamed. The eruption was treated blandly but proved resistant and gradually spread over his entire body. The condition was very pruritic and gradually exfoliation occurred in sheets of epidermis. He lost considerable hair from his scalp, eyebrows, axillae and pubic area. He became very weak and lost from 40 to 50 pounds (18 to 23 Kg.). He had numerous remissions and exacerbations some of which were associated with weeping and oozing.

The original diagnosis was contact dermatitis presumably from rust remover.

In March 1933 the patient consulted Dr. William Allen Pusey of Chicago who made a tentative diagnosis of lymphoblastoma. At this time a biopsy from the skin was taken and proved to be consistent with this opinion. The patient was given some roentgen therapy with no apparent benefit. Since his return home from Chicago he had received no further roentgen therapy and had become much worse.

In 1913 the patient was ill for twelve or thirteen months. He consulted numerous physicians but no final diagnosis was ever made. The symptoms were loss of weight and inability to walk for a time. He gradually recovered. In 1921 he fell from a Pullman berth and dislocated (?) a vertebra. He was an invalid for about nine months but finally recovered. The rest of his past history is unessential.

Examination.—The patient was lying in bed obviously in agony from scratching. There was definite evidence of loss of weight. There was marked thinning of the scalp and eyebrows and practically total alopecia of the axillae and pubic area. There was generalized lymphadenopathy, the largest glands being found in the axillae. These were lemon size and moderately firm but not matted together. The liver was felt a hands breadth below the right costal margin, the edge was hard but not tender. The spleen was questionably palpable. The knee jerks were diminished. The patient presented a universal scaly erythroderma, the scales varying from a branny type over the legs to thicker ones over the back. In areas the skin was thickened and lichenified, but there were no infiltrations or tumors noted. There was marked hyperkeratosis of the palms and soles. A tentative diagnosis of lymphoblastoma was made but it was necessary to substantiate this by biopsy and rule out certain other possibilities.

The blood Wassermann reaction was negative. Urinalysis was essentially negative. Slides were sent to the Simpson Memorial Institute for Medical Research at Ann Arbor, Mich., and the report in part was as follows: There is absolutely no evidence of leukemia. The differential count is as follows: polymorphonuclear neutrophils 65 per cent, eosinophils 18 per cent, large lymphocytes 2 per cent, small lymphocytes 8 per cent, monocytes 7 per cent. This differential count can be accounted for both by a lymphoblastoma such as Hodgkin's disease or as a result of roentgen therapy. Frequent blood counts were made and, although they showed a secondary anemia and an eosinophilia, at no time was there evidence of a leukemic blood picture. Tests for arsenic were negative on the urine, hair and cutaneous scales. Roentgen examination of the lungs September 15 was, according to Dr. J. C. Bell, essentially negative; there was no evidence of enlargement of the mediastinal glands.

Gordon's test (intracerebral inoculation of rabbits) was not performed nor was avian tuberculin employed intracutaneously.

Biopsy.—September 24 a lymph gland was removed from the right inguinal region and with it a piece of the overlying skin. A diagnosis of Hodgkin's disease of the lymph glands was made by Dr. A. J. Miller and corroborated by Dr. Jaffe of Chicago (figs. 1 and 2). Dr. Hamilton Montgomery of the Mayo Clinic reported the following on examination of the skin biopsy (figs. 3 and 4): 'The skin section shows a definite picture of lymphoblastoma nonspecific however, in type. The infiltrate in the upper cutis is too varied and dense and shows too much polymorphism of the individual cells and variation in cell types to permit regarding the picture as a simple inflammatory affair. There are no Dorothy Reed cells present to warrant a diagnosis of Hodgkin's disease, but otherwise the infiltrate together with the eosinophilia would fit in with either Hodgkin's or mycosis fungoides. The usual epidermal changes with microabscess formation seen in mycosis fungoides are absent. The infiltrate is not uniform or dense enough for leukemia cutis or lymphosarcoma, nor does it have enough immature cell forms for these two conditions. In conclusion therefore, I would make a diagnosis of lymphoblastoma, nonspecific in type.' Dr. Gordon, acting pathologist at the University of Michigan Hospital corroborated the diagnosis of a nonspecific lymphoblastoma and added that it might become leukemic at any time.

Treatment and Course.—The patient was entirely too weak to bring into the office for roentgen therapy, so it was necessary

¹² McCartney, J. S., Jr. Malignant Lymphoblastoma. Report of Two Cases. J. Cancer Research 12: 195-207 (Sept.) 1929.

to resort to other local means in order to give him relief from his intractable pruritus. Treatment consisted of wet boric acid dressings continuously and corn starch and baking soda baths. The latter afforded him marked relief from his itching and he gradually spent most of his time in the tub, even eating and sleeping there. Various other local measures were employed, including the usual bland lotions, ointments and powders. In addition he was given calcium, iron and solution of potassium arsenite by mouth. His itching was so intolerable that four or six times the normal sedative dose was of no avail. After several days under the foregoing regimen, roentgen therapy was started. This consisted of generalized superficial therapy as well as high voltage roentgen therapy over the glands. Between September 14 and November 9 the patient received filtered x-ray treatments to the axillary, inguinal and retroperitoneal glands (factors 4 mm aluminum filter 5 milliamperes 135 kilovolt peak distance 16 inches time five minutes, 120 roentgens). In addition he also received generalized and localized superficial therapy between Aug. 29, 1933, and Feb. 12, 1934 (factors no filter, 3 milliamperes, 87 kilovolt peak distance 12 inches, time one minute, 75 roentgens). A 3 mm aluminum filter was employed with this set-up when localized edematous swellings were treated.

The patient made noticeable improvement after three or four roentgen treatments. The relief from the pruritus was remarkable. In spite of improvement in general, there were exacerbations during which the patient would develop chills and fever, and insomnia and would experience a return of the pruritus associated with weeping and oozing of the skin. He also experienced periods of profuse perspiration and developed intermittent edematous swellings over his body as well as some bluish black tumors. He also developed pain and weakness in the right arm apparently due to pressure on the brachial plexus from the enlarged axillary glands.

All of these symptoms gradually subsided, the adenopathy practically disappeared, the liver edge receded and eight weeks after beginning roentgen therapy the patient returned to his work. When I last saw him, Aug. 23, 1934, he was entirely asymptomatic. His skin, according to him, was smoother than he had ever known it to be. His weight was 206 pounds (93 Kg.). There were no appreciably enlarged glands, and the blood count, June 22, 1934, was essentially normal.

COMMENT

There were four major diagnostic possibilities in this case, namely, sensitization dermatitis (contact with an external irritant), an arsenical exfoliative dermatitis, a universal psoriasis, and lymphoblastoma.

Sensitization Dermatitis.—Although there was every reason to suspect such a diagnosis at the onset, the subsequent course and clinical picture were entirely inconsistent with such a diagnosis. The symmetry of the eruption, the keratosis of the palms and soles, the development of subcutaneous nodules, with outbursts of perspiration and fever, and the failure to respond to bland therapy, made such a diagnosis untenable.

Psoriasis.—Occasionally psoriasis is ushered in by a generalized exfoliative dermatitis, and sometimes a typical psoriasis eventually develops an exfoliative stage. There was no history of a previous psoriasis in the case under discussion and the same factors that would rule out a sensitization dermatitis would likewise dismiss this possibility. In addition, the cutaneous biopsy was not the picture encountered in psoriasis, and of course such a condition could hardly explain the lymph gland picture of Hodgkin's disease.

Arsenical Exfoliative Dermatitis.—The generalized exfoliative dermatitis along with the loss of hair and keratoses of the palms and soles would certainly rouse suspicion of arsenism. There was evidence, however, against such a diagnosis. There was no history of arsenic ingestion, arsenic was not demonstrated in the urine, hair, nails or cutaneous scrapings, and there

were no other signs or symptoms of arsenic poisoning. Add to this lack of evidence the edematous nodules found in the skin and the information gleaned from the biopsy of skin and lymph glands, and one is forced to exclude this from the diagnostic possibilities.

Lymphoblastoma.—The presence of a generalized exfoliative dermatitis along with a palpable liver, generalized lymphadenopathy, loss of weight, fever, and development of subcutaneous nodules, was in itself sufficient to place the diagnosis in the group of lymphoblastomas. The cutaneous biopsy definitely showed a nonspecific lymphoblastomatous infiltrate whereas the lymph gland was even more specific, permitting a diagnosis of Hodgkin's disease. Had it been possible to secure a biopsy from one of the bluish tumors or subcutaneous nodules, no doubt a typical Hodgkin's architecture would have been found. According to Rulison,¹³ 25 per cent of all cases of Hodgkin's disease show skin manifestations, and in 10 per cent of the cases the cutaneous are the first symptoms.

Cutaneous Hodgkin's disease can be divided into two types: the essential type, in which there are definite plaques and nodules with a typical Hodgkin's picture microscopically, and the so-called nonspecific type, in which one finds prurigo-like nodules, excoriations, pigmentation, and a generalized exfoliative dermatitis. The latter are usually toxic manifestations and, as a rule, do not show the typical microscopic changes of Hodgkin's disease, although at times they may. The microscopic changes, however, are not always constant, varying at times from a simple inflammatory process to a typical lymphoblastomatous infiltrate with Dorothy Reed cells.

Cole¹³ placed the order of frequency of signs and symptoms in Hodgkin's as follows: diffuse exfoliative dermatitis, pruritus, prurigo-like eruptions, urticaria, edematous swellings, pigmentation, outbursts of perspiration, alopecia, dryness of the skin, icterus, purpuric lesions and red or bluish tumors of the skin. In the case here reported, all these manifestations except icterus were present at some time or other.

Wile and Stile's⁶ paper has shown that the prognosis in such cases is better than heretofore believed. Their patient has already lived eighteen years since the diagnosis was first made.

At the present time our patient is in a state of remission, is entirely asymptomatic, and is enjoying excellent health. No one can predict the future course. Whether or not he will eventually develop typical clinical Hodgkin's disease, the tumors of mycosis fungoides, lymphosarcoma, or the blood picture of leukemia is not known, but no doubt one of these will eventually transpire.

CONCLUSIONS

1 In a case of Hodgkin's disease of the skin, the cutaneous manifestations were the first symptoms, preceding the fever and adenopathy.

2 Every case of generalized exfoliative dermatitis or universal scaly erythroderma should be regarded as a possible cutaneous manifestation of one of the lymphadenoses.

3 The early cutaneous and lymph gland biopsy is of great value.

4 Roentgen therapy to the skin and lymph glands is the most useful form of treatment at the present time.

SUBACUTE COMBINED DEGENERATION
OF THE SPINAL CORD IN
PERNICIOUS ANEMIATHE COMPLETE ARREST OF THE LESION WITH
PARENTERAL LIVER THERAPY

MAURICE B STRAUSS MD

PHILIP SOLOMON MD

ANTOINE J SCHNEIDER, MD

AND

ARTHUR J PATEK JR MD

BOSTON

A survey of the recent literature on the effectiveness of liver therapy in subacute combined degeneration of the spinal cord associated with pernicious anemia reveals grossly contradictory opinions. Seyderhelm¹ believes that this disorder of the nervous system is entirely uninfluenced by such therapy and Cohen², McAlpine,³ Curschmann,⁴ Krause⁵, Fahr⁶, Carey⁷, Davison,⁸ Sargent⁹, Ahrens,¹⁰ Thaysen¹¹ and Morawitz,¹² among others, believe that unfavorable progression of the disease may occur in spite of liver treatment. On the other hand, optimistic reports have been recorded by Minot and Murphy,¹³ Richardson¹⁴, Fried,¹⁵ Ungley and Suzman¹⁶, Suzman¹⁷, Lottig¹⁸, Starr,¹⁹ Strauss and Castle,²⁰ Baker, Bordley and Longcope,²¹ Meulengracht²² and many other clinicians.

Our purpose in this communication is threefold: 1 To consider why such different results have been obtained by various clinicians; 2 To present the data obtained from a critical study of twenty-six patients

with outspoken spinal cord degeneration treated by liver extract injections for an average period of three years; 3 To consider the significance of the fact that spinal cord disease has not developed in any of eighty patients with pernicious anemia while under adequate parenteral liver therapy during an average period of three years, whereas the reported incidence of this condition in pernicious anemia indicates that a significant number of these patients would doubtless have developed spinal cord lesions if untreated during that period of time.

This paper is concerned only with changes referable to the spinal cord. Both the peripheral nerves and the brain may be involved in pernicious anemia, but changes in these parts of the neural system are not for consideration here.

The contradictory reports in the literature may be best understood by considering certain fundamental facts relevant to the spinal cord symptomatology. First of these is the nature of the pathologic lesions. Fried's summation¹⁴ seems sufficient: "Indeed, the pathologic process, like the clinical picture, passes through a series of nuances from barely demonstrable degenerative changes to a complete degeneration of nerve cells and axon cylinders followed by a gliosis." Later he states: "Whereas in visceral organs degenerative cellular changes are often followed by a *restitutio ad integrum*, analogous processes of regeneration of nerve cells or nerve fibers in the central nervous system have never been observed." Regeneration of completely destroyed nerve cells and fibers of the central nervous system following any therapy cannot be expected in subacute combined degeneration of the spinal cord any more than in tabes dorsalis or paralytic poliomyelitis. It is true, however, that in both the latter conditions provided renewed injury is prevented much improvement may be expected over a long period of time through reeducation and because it is possible that unaffected cells and fibers may take over functions previously mediated by destroyed pathways. While it is apparent that a nerve cell or fiber in the central nervous system cannot regenerate when completely destroyed, it appears probable that function may be lost to a greater or less extent in the early stages of the disease process while regeneration is still possible.

These considerations lead to the conclusion that the effectiveness of therapy in subacute combined degeneration of the spinal cord must be determined not by the degree of improvement but by the evidence of arrest of the process.

Secondly, apparent improvement in the neurologic condition may be entirely due to betterment of general health and strength, reeducation and training, and improved circulation and subsidence of edema in the spinal cord. In fact, many of the reports that indicate remarkable improvement in patients with spinal cord lesions fail to consider the fact that when the patients were first observed they often suffered from severe anemia and other manifestations of the deficiency state as well as from spinal cord lesions. Marked improvement in such individuals following liver therapy has no necessary significance with regard to the state of the spinal cord cells or nerve fibers.

Furthermore, since peripheral nerves are capable of complete regeneration as long as the cell body has not degenerated, signs and symptoms referable to such peripheral nerve injury may completely disappear and lead to the impression that marked regeneration has occurred in the spinal cord.

The third point to be borne in mind is that sepsis has a deleterious effect on many kinds of spinal cord lesions and may inhibit the effect of liver therapy in pernicious anemia not only on the spinal cord but on the blood. The study of Cobb and Coleman²³ suggests that the healing of traumatic lesions of the spinal cord may be delayed by the presence of cystitis. Patients with decubitus ulcers and sloughs, those with pronounced urinary tract infections secondary to "cord bladders" and those with other severe febrile septic conditions usually have poor prognoses. The fact that such patients do not do well is not to be construed as meaning that liver therapy has no effect on the spinal cord but rather that it has no effect on sepsis.

The fourth and probably most important consideration is the fact that there is no "standard" dose of liver, stomach or their products, nor is the "usual" dose adequate for many patients. "Adequate" by dictionary definition means "sufficient for some (specific) requirement." When oral therapy is employed it is not uncommon to find that patients cannot ingest a sufficient amount of potent material for their individual needs because of nausea, vomiting or diarrhea produced in some instances by the large amounts of liver or liver extract. Although the exceptional patient may be able to take more, 400 Gm of fresh liver or the extract derived from 1,000 Gm of liver is about the maximum daily amount that can be continued indefinitely by mouth without producing distaste or nausea.²⁴ The fact that even these quantities fail to maintain the blood at a normal level in a significant number of cases, about 5 per cent according to Beebe and Lewis²⁵ makes it apparent that some patients cannot receive without great difficulty enough potent material by mouth. As more potent material is often required to influence spinal cord lesions than to improve the blood, it becomes apparent that many patients cannot ingest satisfactory amounts of potent material for their given cases.

In this clinic we have encountered patients who were showing unfavorable progression of their spinal cord lesions in spite of the fact that they were taking all the liver and liver extract it was found possible for them to ingest. That their unfavorable course was due to the inadequacy of even the massive amounts that they took by mouth was clearly evidenced in eight of our twenty-six cases by the favorable course of events following the parenteral injection of liver extract equivalent in hematopoietic effectiveness to still greater quantities of orally administered material. Many of the unfavorable reports in the literature are without doubt due to the failure to realize that there is no "standard" dose of liver and may well be compared to unfavorable results that would be obtained in diabetes mellitus if all patients were given a "standard" dose of insulin. In the latter disease, failure to control the blood sugar level with a certain dose of insulin usually is considered indicative not that insulin is ineffective but that more insulin is required. In subacute combined degeneration of the spinal cord it must similarly be understood that the failure to arrest the progress of the lesion in an appropriate period of time nearly always means that more liver, stomach or allied potent material is required unless such severe infection or damage to vital organs is present that arrest cannot be

achieved. That arrest is possible in the absence of such factors is evidenced by the data to be presented.

A fifth possible reason for disagreement in the statements of the literature lies in the recording of results obtained over too brief periods of time. When one recalls that many months may be required for the regeneration of a peripheral nerve following trauma or neuritis, it is obvious that conclusions cannot be drawn from short periods of observation of a disease that involves destruction of fibers within the central nervous system. The shortest period of observation in any of the cases reported on here was fourteen months.

PROCEDURE

Woltman,²⁶ Schilling,²⁷ Ahrens,¹⁰ Smithburn and Zerfas²⁸ and other physicians have noted the occurrence of neural symptoms in from 80 to 100 per cent of patients with pernicious anemia. Many of the patients, however, have no more than paresthesias and slight changes in proprioceptive sensation. Suzman¹ determined that although 73 per cent of his series of pernicious anemia patients had neural symptoms, only 41 per cent were suffering from subacute combined degeneration of the spinal cord. Young²⁹ found that 20 per cent of his 515 patients with pernicious anemia had well defined spinal cord disease marked by reflex changes and ataxia, although many other patients had lesser changes referable to the neural system. In order to evaluate results of therapy, we selected for special study twenty-six consecutive patients who had spasticity or ataxia, or both, resulting in definite disturbances in locomotion, in short, patients who had at least moderately severe degeneration of the spinal cord. Without exception these patients also had paresthesias in the hands and feet and all had either diminished or absent vibratory sense in the legs and moderate to marked muscle weakness. Impotence not due to age, or sphincter disturbances, were encountered in five patients. Girdle sensations were common. Patients with decubitus or pronounced urinary tract infections were excluded in selecting these twenty-six cases. For this study we have evaluated the "initial" status of the spinal cord involvement only after the erythrocytes were 3.5 million per cubic millimeter or more. During the period when the "initial" neurologic status of the twenty-six patients was being evaluated the average erythrocyte count was 4.30 millions per cubic millimeter, the hemoglobin 84.6 per cent (13.18 Gm per hundred cubic centimeters) and the color index 0.98. At the time of final evaluation of the neurologic status the average erythrocyte count was 4.78 millions per cubic millimeter, the hemoglobin 94.6 per cent (14.74 Gm per hundred cubic centimeters), and the color index 0.98. Many patients showed striking improvement in signs and symptoms referable to the neural system during the one or two months when the erythrocytes were increasing from low levels to above 3.5 millions per cubic millimeter. Although it is probable that the most effective opportunity for neutralizing the physiologic damage to the neural system would be at this time, data on the improvement during this period of rapid

regeneration of blood have been excluded, since such betterment might have been due to the relief of the anemia, its attendant physiologic alterations and the acute deficiency state in general, hence any conclusions based on such improvement would be open to serious criticism.

Since there occur fluctuations in neurologic signs and symptoms from day to day that cannot be related to significant anatomic spinal cord changes three successive examinations over a period of from one to two months were made after the patients' red blood cells had reached a level of 3.5 millions or more per cubic millimeter. Abnormalities persisting at each of these three examinations were considered significant. Similarly three examinations over a period of from one to two months were made from one to four years later. During the intervening period patients were examined neurologically every three to four months. In general, these neurologic examinations were made by two of us who had no particular further knowledge of the patient's blood, details of treatment, and the like.

As has already been mentioned, eight of the twenty-six patients had had a progression of their neurologic manifestations prior to the time the present observations were begun and while they were taking as much liver or liver extract as they could be made to ingest. This 30 per cent incidence of highly resistant cases among our twenty-six cases, all with advanced spinal cord lesions, is probably from four to six times as great as would be encountered in a consecutive series of pernicious anemia cases. Although it is possible that this incidence of highly resistant cases with advanced spinal cord lesions is higher than would occur in a larger series of such cases, it is probable that it represents the approximate actual incidence of such cases, although one should recognize that difficult cases are more frequently referred to a clinic than simple ones. The neurologic condition of another eight of the twenty-six cases under oral liver therapy was essentially stationary. Ten were improving coincidentally with the remission of their anemia. Nineteen of the twenty-six patients had had neurologic manifestations for over a year, one for at least seven years. Seven patients had had neural symptoms for less than a year.

Treatment in all patients consisted of the intramuscular injection of Solution Liver Extract-Lilly (N N R).³⁰ This material is an aqueous solution of "fraction G" of Cohn, Minot and their associates,³¹ prepared according to the method of Strauss, Taylor and Castle.³² Five cubic centimeters of this solution of liver extract is derived from 25 Gm of liver and is approximately 100 times as hematopoietically effective by injection as by mouth,³³ which may also be true in respect to its effect on spinal cord lesions. Since neither the amount of liver from which an extract is derived nor the quantity of liquid in which it is dissolved indicates the potency of the product, the only suitable means at present of evaluating the latter lies in the determination of the minimum amount of extract that will produce an approximately maximal reticulocyte response in appropriate cases of pernicious anemia in

relapse.³⁴ Approximately 5 to 10 cc. of the extract employed derived from 25 to 50 Gm of liver, may produce such a response when given in one dose,²⁰ but it often takes more than this amount to produce a maximal response in resistant cases.²⁰ Six of the patients either injected themselves or had members of their families do so for them. These individuals usually took for one dose from 2 to 5 cc of the liver extract solution. The remaining twenty patients received their liver extract in the clinic 10 cc being injected into the gluteal muscles at a time. The average amount of extract received per week by the twenty-six patients was 10 cc. The maximum amount given to any patient was 10 cc twice a week and the minimum 10 cc once in three weeks. The key note of the treatment of these patients was that, no matter how much liver extract was being given the amount was increased whenever the progress of the patient was unsatisfactory.

These patients given parenterally the extract, on the average, derived from 50 Gm of liver per week received approximately the equivalent of the same extract for oral use derived from 5,000 Gm of liver per week, or 714 Gm per day, which is about 50 per cent more than the amount taken by mouth by many patients. It is our belief that the results recorded were not due to any specific or peculiar virtue of intramuscular injection but rather to the larger equivalent amounts that were administered as compared to the usual orally treated patient. It is of course also true that parenteral therapy eliminates the possibility of faulty gastro-intestinal absorption.

RESULTS

For the sake of brevity and clarity the results of approximately 300 neurologic examinations made on the twenty-six patients are summarized in table 1. The average period of time elapsing before the final evaluation of neurologic signs was 34 months, varying from fourteen to forty-six months. Changes in neurologic signs of the upper extremities are not recorded in the table. In general, these signs have paralleled but with a lesser degree of abnormality, those referable to the legs.

Three main points stand out clearly in this tabulation. First, and of greatest significance, is that in no instance did a single objective neurologic sign become more marked during the period of treatment, nor did an abnormal sign, not previously present, appear. Complete objective arrest of the lesion has occurred in every case.

Second, subjective improvement of a greater or less degree appeared in every patient. In two patients this was very slight. In others it enabled previously bedridden individuals to return to their usual occupation. Nevertheless such changes may be due entirely to reeducation and training achieved in the presence of a definite, but completely arrested, spinal cord lesion. It is to be emphasized again that the tremendous gains in strength and activity often observed in such cases are not necessarily evidence of regeneration of the spinal cord fibers or cells.

Third, excluding changes in gait and paresthesias, approximately 58 per cent of all the abnormal signs encountered in the twenty-six patients remained objectively unchanged (table 2). Seventeen per cent of all the abnormal signs disappeared and 25 per cent of such signs were present in less intensity. When the

TABLE 1—The Results of Parenteral Liver Therapy in Twenty-Six Cases of Pernicious Anemia with Subacute Combined Degeneration of the Spinal Cord

Case Sex Age Years	Time of Examination	Red Blood Cells Millions per Cu Mm	Hemoglobin per Cent	Abnormality of Gait	Romberg's Sign	Incoordination	Position Sense	Vibratory Sense	Paresthesias	Knee Jerks	Ankle Jerks	Babinski's Sign	Subjective Changes at End of Period Indicated
1 ♂ 36	Initial exam 46 mos later	3.50 5.02	71 85	+ /	N /	N /	- -	- -	++ /	++ +	++ +	N N	Very much stronger walks several miles daily has returned to work. Iridio and potentia absent 18 mos., have returned
2 ♀ 54	Initial exam 44 mos later	4.38 4.50	75 95	+++ +++	N /	++ ++	- -	- -	+ /	++ ++	++ ++	+ +	Stronger walks much better is able to go about unassisted
3 ♂ 52	Initial exam 41 mos later	4.62 4.86	85 101	++ +	+	N /	N -	- -	++ +	N /	- -	N N	Stronger Iridio and potentia absent for 3 yrs., have returned
4 ♂ 57	Initial exam 40 mos later	4.42 5.47	71 85	+ +	+	+	- N	- -	++ +	N /	- -	N N	Stronger walk* better
5 ♂ 78	Initial exam 40 mos later	4.57 4.81	86 95	+ +	N /	+	- -	- -	++ +	- -	- -	N N	Pronounced gain in strength walks more easily
6 ♀ 59	Initial exam 40 mos later	6.23 5.10	102 101	+++ +++	++ ++	+++ +	- -	- -	++ +	++ ++	- N	+ +	Markedly stronger less staggering can do own housework
7 ♂ 70	Initial exam 39 mos later	4.01 5.20	87 104	+ /	N /	++ ++	N -	- -	+ /	+++ ++	++ ++	+ +	Patient was entirely disabled now walks easily feels strong and considers himself entirely normal
8 ♂ 51	Initial exam 39 mos later	3.85 4.78	90 105	+ +	N /	N /	N -	- -	+ /	++ ++	++ ++	N N	Striking gain in strength and ability to walk
9 ♀ 42	Initial exam 39 mos later	3.74 4.07	71 84	+ +	+	+	- -	- -	+ /	++ ++	- +	+ N	Stronger walks better climbs stairs now without aid
10 ♂ 29	Initial exam 39 mos later	4.40 4.84	92 85	+ /	N /	+	- -	- -	++ +	++ /	++ +	N N	Very much stronger walks normally Iridio and potentia absent 6 mos. have returned, is back at work
11 ♀ 46	Initial exam 39 mos later	3.74 4.32	83 87	+ +	N /	N /	N -	- -	+ /	+ +	N N	N N	Very marked improvement in strength and ability to walk can again climb ladders no further urinary disturbances
12 ♂ 50	Initial exam 38 mos later	4.18 4.90	85 97	+++ +	++ +	+++ ++	- -	- -	++ /	N /	N N	+ +	Great increase in strength walks easily without a cane considers himself entirely well Much stronger walks better
13 ♂ 59	Initial exam 38 mos later	4.08 5.04	86 110	+++ ++	+++ ++	+	- -	- -	++ +	++++ ++++	++++ ++++	+ +	Pronounced improvement in strength walks much better feels more solid on feet has returned to work
14 ♂ 32	Initial exam 28 mos later	5.17 4.97	90 105	++ ++	+	++ ++	- -	- -	++ /	++++ ++++	++++ ++++	+ +	Marked gain in strength and ability to walk has been able to return to work
15 ♂ 68	Initial exam 35 mos later	4.01 4.82	90 104	+ +	N /	N /	N -	- -	+++ +	+ +	- N	N /	Slightly stronger walks somewhat steadier
16 ♂ 71	Initial exam 25 mos later	3.68 4.65	85 87	+++ +++	++ ++	+++ +++	- -	- -	+ /	++ ++	++ ++	+ +	Marked gain in strength, walks much better, steadier on feet
17 ♂ 32	Initial exam 33 mos later	4.00 4.74	94 96	++ /	++ +	+	- -	- -	++ /	++ +	- N	N /	Complete disappearance of all symptoms This patient's cord lesions developed acutely while he was receiving inadequate parenteral liver therapy. remission commenced soon after adequate parenteral therapy
18 ♂ 65	Initial exam 31 mos later	3.71 4.50	83 90	++ /	++ /	+	N -	- -	++ +	- /	- -	N /	Very great improvement generally
19 ♀ 62	Initial exam 29 mos later	4.28 4.56	81 95	+ /	+	+	- -	- -	+ /	+	N N	N N	Patient formerly bedridden now walks about house unaided was incontinent now normal this patient also had a definite multiple peripheral neuritis
20 ♀ 40	Initial exam 25 mos later	3.71 4.66	81 81	++++ ++	++ ++	+++ +	- -	- -	++ /	- /	- -	++ +	Patient considers herself entirely normal
21 ♀ 42	Initial exam 28 mos later	4.24 4.55	85 86	+ /	N /	+	- -	- -	+	++ +	++ /	N /	Very much stronger walks better
22 ♀ 62	Initial exam 27 mos later	3.76 4.44	85 94	+ /	N /	+	- -	- -	++ +	++ +	++ +	+ +	Considerable gain in strength and ability to walk
23 ♀ 32	Initial exam 27 mos later	4.29 4.58	80 96	+ /	N /	+	N -	- -	+ /	+	+	N /	Stronger walks better finer movements of hands much improved
24 ♂ 65	Initial exam 26 mos later	4.21 4.86	76 101	+ /	N /	+	N -	- -	++ +	N /	N /	N /	No change except for slight increase in strength and the disappearance of incontinence
25 ♂ 57	Initial exam 25 mos later	5.28 4.48	115 94	+++ +++	++ ++	+++ +++	- -	- -	+ /	++ ++	++ ++	+ +	Was bedridden can now walk with difficulty
26 ♀ 54	Initial exam 14 mos later	5.04 5.10	92 91	+++ +++	++ ++	+++ +++	- -	- -	+ /	+++ +++	+++ +++	+ +	

N signifies normal
The degree of abnormality is indicated by the number of plus or minus sign. Four minus signs indicate the absence of the reflex or sensation
Conditions designated Initial were persistently present on three successive neurologic examinations made after the patient's erythrocyte level was 3.5 million per cubic millimeter or higher
The conditions recorded from fourteen to forty six months later were persistently present on three successive neurologic examinations made after that many months of parenteral liver therapy

nature of the spinal cord lesions is considered, the remarkable fact is not that such a small number of signs decreased in intensity or became normal but that any should have done so at all. Patient 18 is of particular interest since severe neurologic symptoms and signs developed very acutely while he was receiving inadequate parenteral liver therapy. Within a month of the onset of the neural symptoms he was given intramuscularly each week the extract derived from 50 Gm of liver. The final neurologic examination in this case showed a return to normal of all signs except that the achilles tendon reflexes and vibration sense at the ankles remained absent. This state of affairs has been repeatedly seen in other cases not included in the series of twenty-six. We believe thus that, the sooner adequate treatment is commenced after the onset of neural symptoms and signs, the greater the probability for a complete disappearance of abnormal signs, whereas such signs that have been present for over a year seldom disappear entirely.

Of additional importance are observations at this clinic on eighty other patients with pernicious anemia who have been treated similarly with parenteral injections of liver extract. These patients had in many instances evidences of mild spinal cord lesions not interfering significantly with their ability to walk. Other cases showed no objective abnormal neurologic signs. These eighty patients have been treated with liver extract parenterally for from twenty-four to forty-eight months. The average length of treatment has been three years. It is statistically certain, as mentioned at the beginning of this paper, that a number of these eighty patients would have developed spinal cord lesions or had their lesions progress within this period of time if untreated, and from our own experience it is certain that a smaller number would have developed such lesions if treated inadequately by mouth. In not one of these eighty patients has any further evidence of neural lesions appeared. It is therefore apparent that adequate parenteral liver therapy not only arrests the progress of spinal cord degeneration but prevents its development in pernicious anemia.

COMMENT

These data should not be construed to indicate that satisfactory results in the treatment of subacute combined degeneration of the spinal cord may not be obtained with oral therapy, whether by liver, liver extracts, desiccated stomach or other sources of potent material. The experience in this clinic as well as that of many other clinicians has indicated that treatment by the oral route has left nothing further to be gained from parenteral therapy in many cases. Although we know of numerous patients treated orally for more than seven years whose neurologic manifestations have not advanced, we know of no significant number of consecutive cases so treated in which not one patient has become worse. The fact remains that certain patients do become worse while taking all the potent material by mouth that they can ingest and retain. This state of affairs has been repeatedly described in the literature.

It has been suggested from time to time³⁵ that whole liver, desiccated stomach, and brain are superior to extracts of liver in the oral treatment of spinal cord lesions, but no one has published conclusive evidence of this. Often no proper comparisons have been made of the potency of the products used and many instances

can be found recorded in the literature³⁶ in which it appears probable that the effects of large doses of potent material in the form of desiccated stomach are compared with the effects of liver extract in much smaller potent dosage. As has been previously pointed out, the actual potency of the material employed, not the quantity of raw material from which it is derived, is the important factor in making a comparison. Sargent³⁷ has even suggested that a massive amount of iron is more effective than liver therapy. His data, however, cannot be considered satisfactory, because of his failure to take into consideration the points discussed in the introduction of this paper, and also because of the fact that liver had frequently been employed immediately before iron therapy was commenced in many of his cases. The results we have recorded indicate that entirely satisfactory results may be obtained uniformly with an extract of liver when it

TABLE 2—Summary of Changes in Abnormal Neurologic Signs Referable to the Legs Following Treatment of Subacute Combined Spinal Cord Degeneration in Twenty-Six Patients with Pernicious Anemia

Neurologic Sign	Initial Examination	Final Examination			
		Number of Patients with No Longer Present Abnormal Sign	Number of Patients Showing Improvement with Regard to Abnormal Sign	Number of Patients Showing Abnormal Sign Unchanged	Per Cent of Patients in Whom no Change in Abnormal Sign Occurred
Positive Romberg's sign	14	13	10	10	71

Conditions designated initial were persistently present in three successive neurologic examinations made after the patient's erythrocyte level was 3.5 millions per cubic centimeter or higher.

Conditions designated final were persistently present in three successive neurologic examinations made after from fourteen to forty-six months of parenteral liver extract therapy.

is given parenterally in adequate amounts for the given individual case.

The practical application of this study is obvious. First, patients with pernicious anemia while under oral treatment should be carefully observed for the development of symptoms or signs referable to abnormality of the spinal cord and other parts of the neural system quite as much as they should be watched for abnormalities of the blood, tongue, gastro-intestinal tract, and the like. Should neural manifestations appear, one can surely arrest the process very rapidly by instituting adequate parenteral liver therapy. Secondly, patients with distinct spinal cord lesions who have not been previously treated should at once have parenteral liver therapy. Although many such individuals would make

satisfactory progress with adequate oral therapy, the uniformity of good results obtained with parenteral treatment makes this the method of choice. Failure to arrest the process with such therapy must be taken to mean that inadequate amounts of potent extract are being employed. The essential factor in any form of treatment of subacute combined degeneration of the spinal cord in pernicious anemia must rest in individualization of the therapy to suit the needs of each patient. This must be borne in mind in considering the following routine.

In commencing the management of a previously untreated patient our usual procedure is to inject intramuscularly 10 cc of extract derived from 50 Gm of liver every three to four days during the first two to three weeks, followed by weekly injections of the same amount for the remainder of the first year. If satisfactory results have been obtained with regard to every aspect of the disease for a year, one may then reduce the amount to 10 cc every second week, watching the patient with extreme care for any signs of relapse, however slight relating to any system of the body. Should a single such manifestation appear weekly injections of 10 cc are at once resumed and continued indefinitely. Patients who have proved resistant to the usual amounts of potent material given orally are, as a rule, injected with 10 cc of the liver extract each week for at least eighteen months and then the amount may be reduced, with observation of the precautions noted. Those patients however who have proved resistant to large amounts of potent material given orally are usually injected with 10 cc of the liver extract twice each week for at least two years and preferably much longer. The state of the individual patient at the end of such a period must be carefully evaluated in order to decide whether it is safe to reduce this dose. Although more than 20 cc of the liver extract (derived from 100 Gm of liver) per week has not been given in any of the twenty-six cases critically studied, there are cases that require more than this amount to arrest the unfavorable progress of spinal cord lesions, especially if infection or arteriosclerosis is present. It must not be forgotten, of course, that when one takes care of a patient suffering from the spinal cord lesions of pernicious anemia one must do more than see to it that the patient receives adequate amounts of potent material for his given case. The physician must treat the patient, not merely the blood and neural systems.

SUMMARY

1 Twenty-six patients with pernicious anemia and advanced subacute combined degeneration of the spinal cord were treated by the intramuscular injection of liver extract for an average period of thirty-four months. The amount of extract given varied but was selected for each patient so as to be enough to accomplish the desired effect. Complete arrest of the neural lesions occurred in every case.

2 Eighty other patients with pernicious anemia and little or no neurologic disturbances were treated in the same manner over an average period of three years. In none of these patients was there any evidence that spinal cord lesions progressed or developed under treatment.

CONCLUSION

By means of appropriate parenteral liver extract therapy for each case, the spinal cord lesions of pernicious anemia may be prevented from developing or, having appeared, may be completely arrested.

RATE OF BLOOD FLOW IN PATIENTS RECEIVING DINITROPHENOL

HAROLD ROSENBLUM, MD

SAN FRANCISCO

Blumgart and his co-workers¹ have shown the close relationship that exists between the height of the metabolic rate and the velocity of the blood flow. This relationship was demonstrated on hypothyroid and hyperthyroid patients with the use of the radium method² for the determination of the speed of the flow of blood. These observations were abundantly confirmed by Tarr, Oppenheimer and Sager³ and by Gargill,^{3a} who used the sodium dehydrocholate method⁴ in studying circulation time.

The conception that the amount of work done by the heart is partly determined by the metabolic rate has been substantiated and clinically applied in recent years. It has become a well established fact that when senous heart disease is associated with hyperthyroidism the cardiac embarrassment is grossly aggravated when the level of the metabolism is high and is much improved when the metabolic rate is lowered.⁵ This improvement follows naturally after a procedure that lightens the heart's load through reduction of the basal metabolic rate, with consequent lowering of the cardiac rate,⁶ minute volume output of the heart⁷ and the velocity of the blood flow.¹ This conception has been further applied in the treatment of intractable cardiac failure, either congestive or anginal, by means of complete removal of the normal thyroid gland.⁸ Improvement in the cardiac symptoms follows with the fall in the level of the basal metabolism from normal to subnormal.

Since this clear-cut association has been both logical and clinically useful, it seemed highly important to determine whether an appreciable raising of the basal metabolism with alpha-dinitrophenol would affect the dynamics of the circulation as does hyperthyroidism. Tainter's statement that dinitrophenol had been given safely to three patients suffering from angina pectoris⁹ was quite provocative, because of the occasional disaster that follows the administration of thyroid substances to patients with coronary sclerosis and coincidental my-

edema, occasionally even before the basal metabolic rate has reached a normal level¹⁰

There has been a certain amount of evidence that the actions of thyroid substances and dinitrophenol are not similar except for their common ability to increase the metabolic rate. For instance, dinitrophenol does not afford symptomatic relief to patients suffering from hypothyroidism, even though the rate of the metabolism is brought up to normal¹¹. Furthermore, when the metabolism of a patient is raised above normal with dinitrophenol, anxiety, palpitation and tremor (as seen in hyperthyroidism) do not occur,¹¹ nor is there any change in blood pressure, pulse rate or temperature when doses of the drug are kept within therapeutic limits¹². Further, there is no correlation between the metabolic rate and the blood cholesterol concentration when dinitrophenol is used to elevate metabolism¹¹. Also, Cutting and Tainter¹³ have shown that the drug does not accelerate the development of tadpoles as does thyroxine. On the other hand Hall and his associates¹⁴ making use of the Fick principle in three experiments on anesthetized dogs, concluded that the minute volume output of the heart was increased following dinitrophenol administration. The figures were rather variable, and the doses of dinitrophenol were massive, being either toxic or lethal. Rabinowitch and Fowler¹⁵ studied cardiac output during dinitrophenol administration in two cases and obtained inconclusive results.

We wished to determine in these experiments whether in patients whose metabolism had been heightened by therapeutic doses of dinitrophenol the speed of the blood flow was increased as it would have been with a similar rise in metabolic rate from hyperthyroidism or from the administration of thyroid substances. The cardiac output itself was not determined in these experiments. Blumgart and his co-workers, however, believe that the velocity of the blood flow is one of the most important factors that make up cardiac strain.⁶ Ventricular rate and blood pressure changes are regarded by them as negligible,¹⁶ and furthermore these have been shown not to be changed by dinitrophenol.¹

PROCEDURE

Observations on the blood velocity were made before, during and after the administration of dinitrophenol on patients who were receiving the drug for the treatment of obesity. The blood velocity was determined by the sodium dehydrocholate method,³ which gives a normal circulatory time (arm to tongue) of from ten to sixteen seconds, the average being thirteen seconds. The blood velocity determinations were always done in duplicate. Sixteen-gauge needles were used and, for each determination 5 cc of a 20 per cent solution of sodium dehydrocholate was injected rapidly into one of the veins of the cubital fossa. The time between the beginning of the injection and the appearance of a bitter taste in the mouth was recorded with a stop watch. These measurements were made under basal conditions immediately following the basal metabolism test, for which the patients had been prepared in the usual way and which were to be used to compare with the blood velocity rate. Notations were also made on the weight, the pulse rate and the electrocardiographic records before and during the period during which dinitrophenol was given.

RESULTS

Basal metabolic rates, followed by measurements of the blood velocity, were determined on twenty-five patients.¹⁸ There were twenty-four women and one man. All the patients at the beginning of treatment were obese. Preliminary orientation experiments had indicated that the presence of obesity made no effect on the circulation time. The ages of the patients varied from 12 to 60 years, the average age being 37.5 years. The patients averaged 193½ pounds (87.8 Kg.) in weight. The basal metabolic rates of these individuals varied from -17 to +16, their average being -1 per cent (Aub-Du Bois Standard). The blood velocity in the patients in this group was within normal limits

Blood Velocity, Basal Metabolic Rate, Pulse Rate and Body Weight Before and After the Administration of Dinitrophenol

	Number of Patients	Average Blood Velocity Seconds	Average Basal Metabolic Rate, per Cent of Normal	Average Pulse Rate per Minute	Average Weight Pounds
Before dinitrophenol	8	12.6	-6	71	210½
After dinitrophenol	8	13.3	+31	70	190½

(between ten and sixteen seconds) in each case. The average blood velocity was 12.4 seconds. Pulse rates were also within normal limits in each case.

Of these twenty-five patients, all were given dinitrophenol, and eight were found who were satisfactory in every respect for contrast before and after dosage with the drug. An examination of the accompanying table will show that, except for the increased rate of metabolism and the reduction in weight, no appreciable change had occurred. The blood velocity (and the pulse rate), in other words, had remained within the established normal levels. Similarly, no differences were obtained in measurements of the blood pressure or in the form of the electrocardiographic curves before and during dosage with dinitrophenol.

¹⁸ Permission to study these patients was granted by Dr. Russell F. Rybins of the Metabolic Department who was using them for another dinitrophenol investigation.

25. studied the relation of the velocity of the blood flow (as measured by the cyanide technique of Robb and Weiss [A. Method for the Measurement of the Velocity of the Pulmonary and Peripheral Venous Blood Flow in Man. Am. Heart J. 8:650 (June) 1933]) to oxygen consumption in schizophrenic patients who were given dinitrophenol. He concluded that there was a decrease in the circulation time when the oxygen consumption was raised. His data and results are difficult to interpret however since the decreased circulation times were actually considerably in excess (by 40.5 per cent) of the measurements which Robb and Weiss considered normal.

COMMENT

The lack of change in the measurements of the dynamics of the circulation in these experiments would indicate that no increased work was placed on the heart by therapeutic doses of dinitrophenol. Thus, the fact that the drug had been given with impunity to patients suffering from anginal failure can be understood. In addition, another difference is shown between the pharmacologic effects of thyroid substances and the effect of dinitrophenol, namely, that dinitrophenol causes no obligatory increased demand on the circulation in either the speed of the blood flow or the cardiac rate as does medication with thyroid.

CONCLUSION

In eight cases studied when the metabolism was normal and again when it had been heightened by dinitrophenol no discernible effects on the blood velocity or pulse rate were found.

STAPHYLOCOCCIC MENINGITIS WITH RECOVERY

JOHN E. DUNLAP, M.D., DALLAS, TEXAS

My purpose in this report is to present a case of *Staphylococcus aureus* meningitis in which a complete recovery was made during treatment with *Staphylococcus aureus* bacteriophage administered intraspinally. Conclusions should not be drawn from one case. A single successfully treated case however seems worthy of being added to the scant literature relative to this almost invariably fatal illness as a series of treated staphylococcic meningitis cases is difficult to obtain. Schless¹ reported the first and only case in detail in the literature of a successfully treated *Staphylococcus aureus* meningitis with bacteriophage administered intraspinally. He used larger amounts of the bacteriophage than were used in the present case but his results were very similar. Stout² reported treating successfully two cases of staphylococcic meningitis with bacteriophage but no details of the case were given.

In this paper no attempt will be made to discuss bacteriophage therapy itself as this has recently been thoroughly and effectively done by Eaton and Bayne-Jones.³ Suffice it to say that its exact nature and mode of operation against infection in man is not yet definitely understood and that its results are often contradictory.

REPORT OF CASE

P. C., a boy aged 8 years seen in his home Oct. 1 1934 had come home from school four days before stating that while playing on a swing he had struck his left knee on the ground and his back on an iron post. He had no fever that day but his mother said that he complained of pain across the back at the level of a small congenital cyst located at the second lumbar vertebra. The left knee was red tender and slightly swollen and the cyst over the spine was slightly inflamed and swollen the mother stated. The next morning he felt fine and had no complaints but in the afternoon his temperature rose to 101 F and remained elevated that night. He was seen by a local physician then who reported that the patient had a rather severe throat infection (The patient complained of sore throat). The physician also noted some rigidity of the neck. The cyst, he stated, seemed to be infected and had a slight

white discharge. Questioning the family revealed that, though the cyst (about the size of a pecan) had been present since birth, it had never given trouble as at the present time, though for several months the child complained of intermittent pain across the lower part of the back. The physician also stated that the left knee seemed swollen and red and that the right parotid was swollen tender and hot. The patient's gums were spongy and infected. The following day the patient felt better except for headache and the temperature was only slightly over 100 in the afternoon. It was on the following day—the fifth since the beginning of the present illness—that I first saw him. He was complaining of severe headaches then. His temperature was 101 F and he was very restless. On examination it was noted that there was marked rigidity of the neck, the head was retracted as far back as it was possible. The knee and parotid appeared normal. There were no petechiae, no splenic enlargement was present and the heart was normal. The cyst was tender and a little red in its center, there was no secretion at the time. The ears were normal. Immediate hospitalization was ordered.

The patient was admitted to Parkland Hospital October 1. A spinal tap on admission revealed cloudy spinal fluid under greatly increasing pressure. A direct smear of the spinal fluid showed gram-positive diplococci. Several groups of four or five organisms in a group were found in a number of smears. This direct smear was made immediately after the spinal tap. The culture of this initial spinal fluid showed pure culture of *Staphylococcus aureus*. All laboratory work was done in the department of Dr. Sanders pathologist at Parkland Hospital. The patient's progress and the spinal fluid changes in the hospital can best be followed in table 1.

Urinalysis was negative except for 2.2 per cent of sugar on two occasions. The initial blood count was white blood cells 15,300, red blood cells, 3,900,000, hemoglobin 80 per cent, polymorphonuclear leukocytes, 76 per cent, large lymphocytes 16 per cent, small lymphocytes, 8 per cent. The blood count on discharge was white blood cells, 7,600, polymorphonuclear leukocytes, 58 per cent, small lymphocytes 36 per cent, large lymphocytes 4 per cent, eosinophils, 2 per cent. The temperature curve during hospitalization is shown in the accompanying chart.

Course of temperature showing a return to normal of the temperature after the second administration of bacteriophage intraspinally.

Test tube experimentation showed specificity of the bacteriophage used for the infecting strain of organism (table 2).

The clinical condition of the patient on admission and for several days thereafter was bad. He was very restless and complained of severe headache. The head was retracted almost between the shoulders, the child was toxic and at times semi-conscious and delirious. He did not vomit, however, and took fluids and nourishment well. His lips were covered with sordes and his mouth and gums were much infected. During his entire stay he was troubled by great abdominal distention. A blood culture was not made because at no time, after hospitalization, was there any evidence of a blood stream infection. Bilateral choking of the disks was observed throughout the illness although at all times a free drainage of spinal fluid was obtained. No tap was bloody and at no time could any direct communica-

tion between cyst and subarachnoid space be demonstrated. There was no discharge from the cyst. The taps were all done in the intervertebral space above the cyst. No evidence of an epidural abscess was obtained. The spinal fluid pressure on discharge was 20 mm of mercury.

Following his discharge after eighteen days in the hospital, the patient remained in bed voluntarily for several weeks complaining of weakness, headaches and inability to walk, also of pain in the flexor leg muscles on attempting to extend his legs completely. Both disks remained choked and the retinal vessels

infection of the meninges by direct extension or by way of the lymphatics from the infected cyst overlying the lumbar spine. The treatment consisted of copious spinal drainage by lumbar taps, approximately twice a day, all the spinal fluid that would drain off until the pressure was below normal, and the early administration intraspinally of *Staphylococcus aureus* bacteriophage, following which the head of the bed was lowered. Acriflavine hydrochloride, 1 4,000 (10 cc.), was also given intraspinally for two injections, but the first negative spinal fluid culture resulted after the administration of the

full for one month. Fluids were limited and magnesium sulphate was given by mouth every other day. Neurologic examination revealed a weakness of the muscles of the left arm and leg, a markedly diminished left knee jerk and a negative Babinski sign. Ankle jerks were present and equal. Nuchal rigidity gradually decreased in intensity. There were complaints at intervals of blurring and double vision. Improvement, however, was steady. Two spinal taps, done at home, were negative. At the present time, three months since the onset of his illness the boy is bright and happy and is going to school. His gait is not quite normal owing to some dragging of the left leg after much walking. There is no muscular contraction

second ampule of bacteriophage and remained negative throughout the duration of the illness. The temperature became normal along with the first negative spinal fluid culture and remained so. One ampule of 5 cc. of the bacteriophage was given daily for five successive days. Test tube experimentation proved that the bacteriophage used was specific for the strain of *Staphylococcus aureus* organism infecting the patient's meninges.

CONTINUOUS SUBARACHNOID DRAINAGE FOR MENINGITIS BY MEANS OF A URETERAL CATHETER

J GRAFTON LOVE M D ROCHESTER MINN

Repeated spinal drainage has proved advantageous in the treatment of meningitis. It occurred to me that the discomfort of repeated lumbar and cisternal punctures could be avoided by introducing a ureteral catheter through a specially constructed spinal cannula into the subarachnoid space and leaving the catheter in place for continuous drainage.

For several years in the neurosurgical service at the Mayo Clinic, a ureteral catheter frequently has been introduced into one of the lateral ventricles either to secure gradual decompression in cases of internal hydrocephalus or to control the increased intracranial pressure associated with hydrocephalus, of patients who had inoperable neoplasms of the brain while they were undergoing roentgen therapy. The ureteral catheter is threaded through a flanged ventricular cannula, previously introduced into the ventricle with its obturator, through a burr hole placed over the posterior horn of one of the lateral ventricles. The ventricles tolerate well the presence of a ureteral catheter and postmortem examination of the brains of patients who have had continuous ventricular drainage by this method

From the Section on Neurologic Surgery the Mayo Clinic

TABLE 2—*Almost Complete Lysis of the Organism in the Fifth Tube Containing 2 cc of the Bacteriophage*

of the leg and the only positive finding is an absent left knee jerk. The disks are both completely normal and he has no headaches. The cyst is small and innocuous in appearance.

SUMMARY

In a case of *Staphylococcus aureus* meningitis in which recovery was complete, the etiology is not certain but appears likely to have been part of a transient bacteremia from a focus in an acute throat infection. The other possibility is

has not given evidence of ependymitis or other untoward development that could have been caused by the presence of the catheter within the ventricle. With this knowledge I felt that it was safe to leave a ureteral catheter in the subarachnoid space for continuous drainage. The needle used is the length of an ordinary lumbar puncture needle and its lumen is large enough to permit passage through it of a number 4 or 5 French ureteral catheter (fig 1). The instrument maker designates the needle Barker's 13 gage. This needle can be introduced without difficulty into the lumbar subarachnoid space or posterior cistern (cisterna cerebellomedullaris). When the needle enters the subarachnoid space the obturator is withdrawn. When fluid is seen to escape and the surgeon is certain that the needle is properly placed, a number 5 flute-tipped ureteral catheter is passed through the needle until the tip of the catheter reaches the inner end of the needle. The length of catheter necessary for this can be determined previous to the puncture by measuring the catheter by means of the obturator. When the catheter has been introduced it is held in position while the needle is withdrawn. It is unnecessary to suture or otherwise fix the catheter, for the tissues through which it passes are so thick and so closely applied to the walls of the catheter that it remains in position without additional fixation. The catheter, which is flexible, is not dislodged even if the patient turns over in bed and lies on his dressing. The catheter is cut off about 3 inches (7.5 cm) from the surface of the skin and a large absorbent dressing is applied over its outer end to absorb the fluid as it drains outward. If the patient is quiet and cooperative as usually he is not when meningitis is present the catheter may be left full length and allowed to drain into a bottle at the side of the bed.

A number 5 French flute-tipped ureteral catheter and special needle

I have not had an opportunity to try this procedure in a sufficiently large group of cases to give statistics to prove its efficacy but in the few cases in which it was used it gave gratifying results, and I expect to use it more in the future.

REPORT OF CASES ILLUSTRATING APPLICATION OF URETERAL CATHETER

CASE 1—Postoperative cerebellar tumor, continuous drainage used to prevent hydrocephalus and necessity of repeated punctures. A white woman, in February 1931, underwent a subtotal resection of a cystic astrocytoma of the left cerebellar lobe. The patient returned in August 1934 at the age of 24, for a second operation, at which time complete resection of an extensive left cerebellar tumor was carried out. Following the operation the patient was febrile and the musculocutaneous flap began to bulge unduly. On the fifth postoperative day, because of the evidence of excess fluid and increased intracranial pressure a flute-tipped ureteral catheter was inserted through the needle into the posterior cistern. Cerebrospinal fluid drained through the catheter until the eleventh postoperative day, when the catheter was removed. There was no further bulging of the flap. The wound healed by primary union. The patient was dismissed seventeen days following radical removal of the cerebellar tumor. Her condition on dismissal was satisfactory. She did not have headaches.

CASE 2—Questionable meningitis (negative culture) continuous lumbar drainage. A white man aged 38 admitted to the hospital in August 1934, stated that he had received two gunshot wounds forty-eight hours previously. One bullet had lodged in the soft tissues of the neck and the other had traversed the spinal canal at the level of the tenth thoracic vertebra resulting in a complete transverse lesion of the spinal cord.

Two days after the patient's admission, he began to complain of headache and stiff neck and of a sense of constriction about the chest. The temperature rose from normal to 100 F, he was perspiring profusely and appeared toxic. Clinically, meningitis had developed. In addition to the stiff neck, fever and evidence of toxemia, examination of spinal fluid disclosed 6,600 polymorphonuclear leukocytes, 80 large lymphocytes and 40 small lymphocytes for each cubic millimeter of fluid. The fluid was grossly turbid. Smears of this fluid did not reveal any organisms, and cultures were reported later as "negative."

Because of the clinical evidence of meningitis and the fact that the patient appeared worse the next day, continuous lumbar subarachnoid drainage was instituted. An olive-tipped ureteral catheter, which had but one opening not placed at the extreme end of the catheter, was used, because a flute-tipped catheter (having three openings with one at the extreme tip) was not immediately available. The patient was soon much more comfortable. The following day his neck was less rigid, his headache had disappeared, and the sense of constriction about the chest of which he had complained was gone. After forty-eight hours of continuous drainage, the ureteral catheter was removed. The patient had shown marked improvement clinically during these two days. Spinal puncture, performed the next day to obtain a specimen of fluid for examination, revealed a very slightly yellowish fluid, which on microscopic examination contained 8 polymorphonuclear leukocytes, 4 large lymphocytes, and 5 small lymphocytes for each cubic millimeter of fluid. A few erythrocytes also were present.

The patient had no further symptoms or signs of meningitis and the course from then on was that of an uncomplicated transverse lesion of the spinal cord. The patient remained under our care for twenty-five days after which he was transferred to his hospital at home for further care. At the time of dismissal his general condition was satisfactory, but he had not regained any power or sensation, which had been lost from the time of the gunshot injury.

CASE 3—Influenzal meningitis. A white boy, aged 3½ years admitted to the hospital July 31, 1934 was suspected of having meningitis.

Lumbar puncture revealed cloudy cerebrospinal fluid and there were 2,503 polymorphonuclear leukocytes for each cubic millimeter of fluid. Gram stain of smears from the fluid disclosed pus cells but no organisms. Cultures of the fluid revealed the presence of *Haemophilus influenzae*. Blood culture was reported as containing small, gram-negative bacilli, probably *Haemophilus influenzae*. Daily lumbar drainage was performed for five days, but this procedure had to be discontinued then for fluid could not be obtained when a spinal puncture needle was introduced into the lumbar subarachnoid space. A ureteral catheter was placed in the posterior cistern (cisterna cerebellomedullaris) according to the technique described for continuous drainage. At the time of institution of continuous drainage, the patient's temperature was 105 F, he was stuporous and entirely uncooperative. The next day he could not move the right upper extremity, and there were "twitchings" of the right side of the face and of the right upper and lower extremities. These manifestations suggested the possibility of a left cerebral abscess particularly because he gave a history of an old infection of the left ear. It also suggested a localized lesion of the left cerebral cortex associated with the meningitis. The catheter in the cistern was draining freely. Two days later clinically, the child was much better. He was conscious and alert and carried on a satisfactory conversation with the examiner. The temperature had dropped to normal and the pulse to 90. This improvement was only temporary, for forty-eight hours later he began to fail rapidly and he died on the twelfth day following admission which was the seventh day following institution of continuous cisternal drainage.

It is questionable in this case whether continuous drainage was of value. However, there was temporary improvement following its adoption and the case proves the practicality of prolonged continuous drainage by means of a catheter placed in the posterior cistern.

The postmortem examination was interesting. The ureteral catheter was patent and lay in the cistern without any local reaction being present. Suppuration in the meninges was minimal and much less than one would ordinarily expect in a

fatal case of meningitis that had lasted for more than twelve days. There was no hydrocephalus, nor was there any cortical or subcortical suppuration (abscess).

CONCLUSION

Continuous subarachnoid drainage can be effected without the necessity of a formal operative procedure and without the danger of the presence of a rigid instrument (needle) left in the back. A ureteral catheter introduced into the subarachnoid space will not cause irritation, and it will obviate the necessity for daily spinal puncture.

GLANDULAR PHYSIOLOGY AND THERAPY

ESTROGENIC HORMONES AND CARCINOGENESIS

LEO LOEB, MD

ST LOUIS

NOTE.—This article and the articles in the previous issues of THE JOURNAL are part of a series published under the auspices of the Council on Pharmacy and Chemistry. Other articles will appear in succeeding issues. When completed the series will be published in book form.—Ed

Three lines of investigation, conducted more or less independently of one another for a number of years, have led recently to the conclusion that a remarkably close relation in chemical constitution as well as in biologic effects exists between estrogenic hormones and certain hydrocarbons that occur in tar and are able to induce cancer. The facts that resulted directly in the formulation of this problem came in part from investigations of Kennaway, Cook and Dodds and their collaborators concerning the chemical constitution of the carcinogenic constituents of tar and the ability of these and related substances to induce estrus and in part from another series of experiments in which it has been shown that estrogenic hormones are factors in the development of certain kinds of cancer. There are then (a) first a series of investigations which beginning with the finding that tar when applied to the skin over a long period of time may induce the development of cancer, led to the isolation of certain substances from tar having the ability themselves to induce cancer formation and to the synthetic preparation of these and related compounds, (b) a second series, beginning with the analysis of the mechanism underlying the sexual cycle, which proceeded to the study of the place of origin, the function and the chemical constitution of the hormones that dominate the various phases of the cycle, and (c) a third series of investigations which concerns the significance of ovarian hormones in the development of mammary cancer in mice.

I shall now discuss briefly these three lines of investigations and the main conclusions to which they lead.

FIRST SERIES OF INVESTIGATIONS

The first series of experiments originated with the discovery by Yamagiwa and Ichikawa¹ in 1915 that long continued applications of tar to the ear skin of

rabbits may initiate cancerous changes in the tissue exposed to the action of this substance. Subsequently, Tsutsui² showed that in mice epidermal cancer can be produced in a much larger percentage of cases than in rabbits and that therefore mice are the more favorable species for testing the carcinogenic power of various substances related to tar. It was next found by Bloch and Dreifuss³ that the compounds present in tar and responsible for the production of cancer are neutral, nitrogen free substances possessing a high boiling point. This led to attempts to isolate the active principles involved. Following Bierich, who believed pyrrole to be active, Kennaway⁴ showed that, if isoprene is exposed to a high temperature in an atmosphere of hydrogen, a mixture of compounds, chiefly aromatic in nature, develops, which has marked carcinogenic power. Carcinogenic substances were likewise produced in a similar way by exposing acetylene and also yeast and human skin to very high temperatures. These investigations suggested that the active substances in this case might be hydrocarbons. Continuing these experiments, Cook, Hewett and Hieger⁵ obtained carcinogenic substances in a pure state, furthermore, Cook and his associates⁶ prepared these substances synthetically and showed that some of them were chemically identical with others extracted from tar. It could also be demonstrated that it is the tricyclic phenanthrene ring system which is common to all these carcinogenic hydrocarbons and that a series of compounds related to 1,2-benzanthracene, which itself is inactive, possesses especially marked carcinogenic properties.

The principal carcinogenic hydrocarbons found so far are (1) 1,2-benzpyrene, which has been isolated from pitch and also synthesized, this is perhaps the most active substance, 4,5-benzpyrene, on the other hand, is inactive. (2) 5,6-cyclopenteno-1,2-benzanthracene, which also is very active. Tumors have been obtained with this substance in rats as well as in mice and some of these tumors have metastasized. (3) 1,2,5,6-dibenzanthracene, which is somewhat less effective in initiating squamous cell carcinomas in mice than the first two substances, injected subcutaneously in mice and rats it caused the production of sarcomas. (4) 9,10-dihydroxy-9,10-di-n-propyl-9,10-dihydro-1,2,5,6-dibenzanthracene. (5) 6-isopropyl-1,2-benzanthracene. (6) Various other derivatives of 1,2,5,6-dibenzanthracene, which are active but less so than 1,2,5,6-dibenzanthracene itself. (7) Chrysene, which is a substance that may give rise to connective tissue tumors when injected into rats and also into mice, but investigators differ somewhat as to its power.

to produce epithelial tumors in mice Bottomley and Twort⁷ have obtained some positive results with this substance. The degree of activity of various compounds, however, depends not only on their chemical constitution but also on the medium in which they are dissolved, in the case of chrysene, Twort showed that if it is dissolved in oleic acid the latter may act as a sensitizer and strengthen the potency of this substance. In general it seems, then, that a molecular structure consisting of rings attached to the 1, 2 and 5, 6 position of the anthracene ring system tends to induce a marked carcinogenic activity.

As far as the etiology of cancer is concerned, this series of investigations indicates that tar and the carcinogenic substances it contains are much more specific in their action than had been previously assumed. Apparently they may induce cancer formation without first causing local irritation. They operate evidently as stimulants of growth. On the other hand, these substances are not selective as regards the substratum in which they act, they may produce a cancerous transformation of epithelial as well as of connective tissue cells. The result depends on the kind of tissue with which they come into direct contact. Furthermore, it seems that they produce cancer not directly, as the agent of Rous sarcoma does, but indirectly. They effect, step by step, changes in the cells on which they act and these changes ultimately eventuate in the formation of cancer from originally normal cells. In this process these carcinogenic compounds differ only quantitatively from a number of other substances or conditions that induce cancer formation in a similar manner, such as arsenic, aniline substances given off by certain parasites and long continued regenerative processes caused by chronic irritation.

These investigations, in defining the chemical constitution of the carcinogenic agents present in tar and that of related synthetically produced compounds, have shown the chemical relationship of such substances to a whole series of other biologically important substances, such as cholesterol, bile acids, ergosterol and vitamin D, their relationship to the testis hormone and above all to the estrus producing hormones that are derived from the ovarian follicles and are present besides in the urine of pregnant women and of pregnant mares has also been demonstrated. However to this class of related compounds belong also substances which, as far as their biologic effects are concerned, are as far removed from the carcinogenic and estrogenic principles as the glucosidic heart stimulants strophanthin and digitoxin, and certain alkaloids (morphine, codeine, colchicine). All these substances as well as the carcinogenic agents possess the phenanthrene ring, they differ from one another in the degree of hydrogenation and in the character of polar groups and of side chains. Because of these relationships between carcinogenic substances and the sterols, which naturally occur in the animal organism, Kennaway and Cook suggested that carcinogenic substances similar to those obtained from tar, such as certain derivatives of 1, 2 benzantracene, might under some conditions arise in the body from sterols normally present in cells as the result of those local interferences that lead to the development of cancer.

SECOND SERIES

Among the various agents mentioned, it is mainly the estrogenic hormones and their relation to the carcinogenic substances that seemed of special interest and gave rise to a series of investigations in which, on the one hand, the estrogenic potency of carcinogenic hydrocarbons and, on the other hand, the possible carcinogenic activity of estrogenic hormones were studied. During the last thirty years a long continued series of experimental investigations has led to the conclusion that in mammals the sexual cycle of the female organism depends on the action of two hormones or of two sets of hormones, namely (1) the follicular hormone, which dominates the first, the follicular phase of the sexual cycle directly preceding and following ovulation, thus causes an active proliferation in the vagina and a more restricted growth in the mucosa of the uterus. (2) The luteal hormone, which dominates the second, the luteal phase of the cycle, this makes possible the placenta formation in the pregnant animal and also induces the predecidual changes in the uterine mucosa, which take place previous to the embedding of the egg and which represent a part process in the placenta formation.⁸ Early extirpation of the corpora lutea prevents these changes.⁹ Moreover, the corpus luteum hormone prevents ovulation¹⁰ and insures the uninterrupted continuation of pregnancy. Of these two hormones or sets of hormones, the follicular hormone was alone at first considered by those who had studied the carcinogenic hydrocarbons of tar and related compounds. This was largely due to the fact that, owing to the investigations especially of Doisy¹¹ and Butenandt,¹² the chemical constitution of estrogenic hormones from the urine of pregnancy had been cleared up, as in the case of the carcinogenic hydrocarbons, so also in the case of theelin and the related estrogenic substances a close relationship to the sterols had been established. The suggestion was made therefore that estrogenic substances might be derived in the body from sterols. Theelin had been found to be a tetracyclic compound which contains one aromatic ring, and, according to Girard,¹³ in the urine of pregnant mares

there occurs another estrogenic substance which contains two aromatic rings (equilenin). The interest in the relationship between estrogenic and carcinogenic substances was further stimulated by the discovery of Aschheim and Hohlweg¹⁴ that in extracts of bituminous material (coal, mineral oil) substances are present that have a definite estrogenic potency. It was obvious that this might be due to compounds related to those which may function as carcinogenic agents. Furthermore, it was pointed out that estrogenic substances can induce active cell proliferation, and lastly it has actually been proved that under certain conditions estrogenic substances may induce or accelerate cancer formation, but the latter observations will be discussed subsequently. Quite recently, Butenandt and Westphal Allen and Wintersteiner,¹⁵ and Fels, Slotta and Ruschig¹⁶ have made it probable that the luteal hormones have a similar chemical constitution to the estrogenic hormones, apparently these are unsaturated phenanthrene derivatives possessing two ketone groups and it appears therefore likely that the facts stated as to chemical relation between carcinogenic compounds and estrogenic hormones apply in addition to the luteal hormones.

Proceeding with these investigations, Cook and Dodds and their associates¹⁷ examined a number of hydrocarbons (in which previously the carcinogenic potency had been analyzed) as to their ability to induce estrus in castrated mice and rats and also to change the plumage in capons in the direction toward female characteristics.

The following are the principal substances that they found estrogenic: (1) 1-keto-1,2,3,4-tetrahydrophenanthrene. This was the first compound of known chemical constitution that was shown to be estrogenic, although to a much less extent than theelin. (2) 1,2,5,6-dibenz-9,10-di-n-butyl anthraquinol. (3) 7-methoxy-1,2-cyclopenteno-phenanthrene, this is identical with the dehydrogenation product of equilenin. (4) The most efficient of these estrogenic substances was 9,10-dihydroxy-9,10-dipropyl-9,10-dihydro-1,2,5,6-dibenzanthracene, a derivative of dibenzanthracene that itself is not estrogenic but becomes so when hydrogenated and supplied with hydroxyl groups. The butyl preparation approaches the propyl derivative in potency, but if other groups are substituted for propyl or butyl, the potency decreases very much or disappears altogether.

Of particular interest is the fact that the two most active carcinogenic substances, (5) 1,2-benzpyrene and (6) 5,6-cyclopenteno-1,2-benzanthracene, are also estrogenic, although their potency is much weaker than that of the dibenzanthracene derivatives mentioned under 4. Likewise (7) dimethylphenanthrene is weakly active. On the other hand 1,2,5,6-dibenzanthracene, which is actively carcinogenic is devoid of estrogenic

potency. Also a number of other phenanthrene derivatives are nonestrogenic. While the saturated cholesterol itself is nonestrogenic, some related, nonsaturated substances, such as neo-ergosterol, vitamin D and ergosterol, are estrogenic.

It seems, then, that the presence of one or two aromatic rings and of an oxygen containing group in the phenanthrene ring is necessary for a compound to acquire a high estrogenic potency, but even in substances not possessing the oxygen containing group, estrogenic activity may be observed, although it is low under these conditions.

In addition it has now been established that even the phenanthrene ring is not necessary for the manifestation of estrogenic potency, 1-keto-1,2,9,4,5,6,7,8-octahydro-anthracene also shows such activity, moreover a low estrogenic potency is shown even by certain highly unsaturated fatty acids.

If these two series of compounds are compared with each other, the first one, representing the substances possessing carcinogenic activity, and the second, consisting of estrogenic compounds, one may conclude that (1) there are substances which are both carcinogenic and estrogenic, (2) there are carcinogenic substances which are not estrogenic, (3) there are estrogenic substances which are not carcinogenic, and (4) even in cases in which compounds are both estrogenic and carcinogenic, there is no parallelism between the strength of these two activities. The substances most potent carcinogenically are not the most potent estrogenic compounds. A special effort has been made recently by Burrows¹⁸ and Kennaway to demonstrate a possible carcinogenic action of theelin when applied to the skin of mice over a long period of time, a method that has been found effective with the carcinogenic hydrocarbons of tar. However, their essential observations, under these conditions, consisted in certain changes in the vagina, uterus and part of the prostate, which might be expected if some of the theelin had been absorbed through the skin or taken in orally by the animals and thus had exerted the usual effects of these hormones on the sex organs. No tumor was produced in this way.

It seems, then, that the relations between the estrogenic and the carcinogenic potencies of certain substances do not differ essentially from the relations between the estrogenic and the rickets preventing activities of other, also chemically related, compounds, these two functions may or may not be exerted by the same substance but, if they are combined, the association is apparently a more or less fortuitous one. Presumably the chemical groups responsible for these various activities are not the same, although the possibility must be considered that a very indirect connection between them may exist so far as certain peculiarities of chemical constitution of the compounds under discussion might favor their marked potency in different, biologically unrelated directions.

THIRD SERIES

While, as stated, theelin does not have a carcinogenic effect if applied in the manner which, when tar and certain hydrocarbons are used, leads to tumor formation in mice, in another way it has been possible to prove that ovarian hormones, in interaction with hereditary factors are responsible in mice for the origin of

mammary cancer, the most frequent tumor in this species. First, it has been shown¹⁹ in breeding experiments (1907-1919) that, in different strains and families kept under the same environmental conditions, the cancer rate varies between almost 100 per cent on the one hand and zero on the other, and that in each strain or family this peculiar cancer rate remains approximately constant in successive generations and is a genetically determined condition. It has furthermore been shown that not only the cancer incidence but also the cancer age is genetically determined and characteristic of each strain. Only on the basis of these data was it possible to analyze the effect of ovarian hormones on the incidence of mammary cancer. If in mice belonging to strains with a known high incidence of cancer the ovaries are extirpated at the age of from 3 to 4 months, the cancer incidence falls to zero in the majority of strains or families and to a ratio approaching zero in others.²⁰ The subsequent experiments of Cori²¹ have proved that if castration is carried out at a still earlier period—two months—the cancer rate is definitely reduced to zero. But when the ovaries were extirpated at successively later periods of life the cancer rate rose correspondingly step by step, until, if the castration took place at the age of from 8 to 10 months the rate became about as high as it was in noncastrated mice. Not only did ovariectomy cause a marked reduction in the incidence of cancer but it also increased the average age at which cancer appeared. Prevention of breeding as a rule also reduced the cancer rate, but to a much less marked degree than ovariectomy. These data were interpreted as indicating that ovarian hormones, acting on the mammary gland in cooperation with hereditary factors, caused the transformation of the normal gland tissue into cancerous tissue. The hormones functioned under these conditions as a stimulant comparable to the action of tar in epidermal and other cancers. The relation between the hereditary (H) and stimulating (S) factors in the production of cancer (C) can be expressed by the equation $H + S$ (or $H \times S = C$).²²

In further experiments the attempt was made to induce cancer formation in animals in which it does not occur under normal conditions, by supplying ovarian hormones. Thus the ovaries of females belonging to the same strains were transplanted into spayed male mice belonging to high cancer rate strains.^{20b} But

cancer did not develop in the males under these conditions, presumably because the ovarian follicles did not function sufficiently after transplantation. Cori likewise obtained negative results.²¹ However, subsequently, Murray,²³ experimenting on a much larger scale, obtained a small percentage of positive results.

Of the ovarian hormones that could be held responsible for this carcinogenic effect there were to be considered (a) the follicular hormone that is active during the follicular phase of the sexual cycle and (b) the luteal hormone that is active during the luteal phase. The principal action that these two hormones exert on uterus and vagina has already been discussed. As to their influence on the mammary gland, the organ with which I am here mainly concerned, it could be shown that the follicular hormone causes proliferation in guinea-pigs, rats and mice.²⁴ In rabbits, Ancel and Bouin²⁵ attributed the growth of this gland to the luteal hormone, however, it was demonstrated that in guinea-pigs a proliferation of the mammary gland does not take place during the luteal phase of the cycle.²⁴ On the basis of these data, I considered primarily the follicular hormone as the carcinogenic agent, but there were also indications that in addition, the luteal hormone might be of significance.²⁶ Cori then attempted to produce cancer in female mice belonging to a high cancer strain and castrated at an early period of life, by the injection of estrogenic hormone at regular intervals over a long period of time. These experiments as well as those continued by him in cooperation with me gave negative results, apparently owing to the use of insufficient doses of this preparation. However, quite recently, Lacassagne²⁷ succeeded by this method but with the use of much larger doses of estrogenic substance (in the form of a benzoate)²⁸ in producing mammary cancer in male mice in which normally it would not have appeared. Thus it is possible also to increase the cancer rate through administration of a derivative of an estrogenic hormone. Lacassagne furthermore found that injections of estrogenic substance eventually led to cancer formation not only in high tumor rate but also in low tumor rate strains,²⁸ although in the latter this effect was accomplished with much greater difficulty.

As stated, under natural conditions the development of mammary cancer in mice depends on the interaction between hereditary factors and an ovarian hormone, acting as a stimulant of tissue growth. The problem arose as to the character of these hereditary conditions. Apparently they act as sensitizers of the tissues, render-

28a Lacassagne²⁷ employed a preparation called "folliculine benzoate". It is impossible to judge from the literature whether this is the benzoate of ketohydroxyestrin (theelin) or whether it is identical with hydroxy estrin benzoate marketed in this country under the name "Progonin B". In his subsequent publication²⁸ Lacassagne designates the product employed simply as "folliculine".—En.

ing them more receptive to the effects of the stimulants. We considered it therefore possible that in cancer-rich strains there might be a stronger response of the sex organs to the estrogenic hormones, leading to modifications of the sexual cycle. However, preliminary experiments in which we²⁹ attempted to demonstrate a constant difference in the sexual cycle between high and low tumor rate strains so far proved negative, but Lacassagne has noted such differences in his recent paper.²⁸

It may now be asked what bearing these investigations have on the interpretation of the first two series, in which the close chemical relationship between the carcinogenic substances present in tar and estrogenic hormones has been demonstrated and in which it has furthermore been shown that certain of these carcinogenic substances are also estrogenic. It may be regarded as established that estrogenic substances, as a rule acting in association with hereditary factors, may be strongly carcinogenic, but such carcinogenic action is restricted to the tissues of the mammary gland with which they combine and in which, under normal conditions, they induce growth processes. The carcinogenic effect of this hormone is thus restricted to secondary sex organs. It is this specific character which distinguishes the action of ovarian hormones from that of the carcinogenic agents present in tar. Such a specificity is very far reaching, it extends in a graded degree even to the sex organs themselves. Thus it could be shown that the follicular hormone induces growth processes in the vagina, and in the vaginal, middle and uterine cervix of the guinea-pig with an intensity that decreases in these organs quantitatively in the order named.³⁰ This specificity relates in the first place to the substratum on which these hormones act and to a less extent to the hormone as such. In the case of the carcinogenic hydrocarbons, on the other hand, such a specificity is much less pronounced, or it may be lacking altogether, they seem to be able to induce the transformation of normal into cancer tissues at any point at which they come into long continued contact with tissues, whether these are of epithelial or of connective tissue origin, provided they still possess the potentiality to grow and proliferate. However, while the induction of growth processes in the organs on which they act specifically is accomplished very rapidly by the estrogenic substances, the cancerous transformation that they cause occurs only after these growth stimuli have had a chance to act over a relatively long period of time. Similarly the carcinogenic hydrocarbons of tar effect the cancerous transformation only after long continued action on the tissues, in which they step by step induce manifestations of increased growth energy. In the case of both estrogenic hormones²² and tar²¹ the definite cancerous transformation is preceded by a preparatory period. When this stage has been reached, the carcinogenic agent whether hormone or tar no longer needs to be applied, the carcinogenic effect follows spontaneously in the course of time. Furthermore, in both cases it can be shown that the longer the stimulus has acted the greater is the incidence of cancer and the earlier the period of life at which it appears.

In both instances the carcinogenic effect is evidently an indirect one, it differs from the growth processes that the ovarian hormones as well as other hormones, such as the thyroid stimulating hormone, induce in the susceptible tissues, and it depends on changes that take place gradually in the cells under the influence of the continued action of these various agents. However, while the hydrocarbons of tar, as well as the estrogenic hormones, may be more efficient than other factors in producing cancer, in principle they do not act differently from the numerous other conditions that may cause cancer following a preliminary period of increased, nonspecific growth processes. Provisionally it may be assumed that all these agents, but with varying readiness, gradually induce changes in the normal cell equilibrium and thus, step by step, transform it into a cancerous equilibrium in which certain growth substances are produced in an increased quantity and perhaps also in a qualitatively modified manner. The latter which, as far as fowl sarcoma is concerned, at the same time may also induce specific tissue transformations,³² continue then to be produced as the result of the changed cell metabolism in a manner that resembles an autocatalytic process. In this connection it may be recalled that Murphy considers the filtrable agent of chicken tumors not as an ultramicroscopic living organism but as a nonliving organic substance. In the case of Rous sarcoma, substances of this nature which are formed in excess in the cancerous cells may be separated from the cells and as such induce the cancerous transformation directly in other cells with which they have combined.³³ However, this interpretation, as stated, must at present be regarded as tentative. There exists the possibility that an extraneous virus, either in combination with cell specific substances or alone, is responsible for this direct, almost instantaneous, cancerous transformation (Gye and Purdy,³⁴ Andrewes³⁵).

SUMMARY

Briefly, the carcinogenic hydrocarbons of tar and related compounds, estrogenic substances as well as certain other factors, in the course of time may induce cancer formation in those tissues on which they act. But while carcinogenic hydrocarbons as well as regenerative processes (irritation) may affect a great variety of tissues, the estrogenic hormones are limited in their action to the tissues in which they induce growth processes during the normal sexual cycle. Both carcinogenic hydrocarbons and ovarian hormones bring about the cancerous transformations of tissues in an indirect manner, they differ in this respect from other agents merely from a quantitative point of view. The mechanism by which ovarian hormones produce proliferative processes in the sex organs differs from the mechanism underlying the cancerous transformation, although the latter may ultimately depend on proliferative processes acting over a long period of time. There exist, therefore, no direct but only indirect connections between the carcinogenic action of the hydrocarbons of tar and the carcinogenic effect produced by estrogenic hormones.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.

CHICAGO

NOTE.—In their elaboration these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The series of articles will be continued from time to time in these columns.—En

THERAPY OF UREMIA (AZOTEMIA)

True uremia is a syndrome the characteristic feature of which is retention of nitrogenous waste products in the system owing to insufficiency of kidney function. It must be distinguished from eclampsia (q v) believed to be due to angiospastic cerebral edema, which may occur without kidney insufficiency, as well as from the cerebral angiospastic ischemia attacks of arteriosclerosis (q v), because the therapy and the prognosis of these three conditions are quite different. Although these various disturbances may occur in all possible combinations, it is not only illogical to speak of "uremia without kidney insufficiency" or "pseudo-uremia," as Volhard, for instance, does but also fatal to the drawing of clear indications for therapy.

DIAGNOSIS

The diagnosis must be based on definite evidence of a considerable degree of retention of waste products of metabolism (direct evidence of uremia) and of marked kidney insufficiency (indirect evidence of uremia), though organic kidney disease is not necessarily present.

The direct evidence rests on the demonstration of a high percentage of nonprotein nitrogen (the nonprotein nitrogen above 66 mg per hundred cubic centimeters), of high blood urea (urea nitrogen above 45 mg per hundred cubic centimeters) and of creatinine (above 3 mg per hundred cubic centimeters). Of great significance is the demonstration of indican (test 1) in the serum, and possibly of still greater importance is that of phenol (test 2) in the serum. This is accompanied by a severe and progressive acidosis, the degree of which is an even better measure of the danger to the nephritic than is nitrogen retention. Hence the necessity of testing the alkali reserve in every case of severe kidney disturbance (see Acidosis).

The indirect evidence is a low fixed specific gravity of the day and the night urine (1.015 or less) and a relatively high volume of night urine (750 cc or more), with a low salt (test 3) and nitrogen concentration and a low phenolsulphonphthalein excretion (25 per cent or less, test 5). Albuminuria and cylindruria are of no value in the recognition of uremia.

An important variety of uremia is that secondary to hypochloridosis, such as occurs most especially as the result of excessive vomiting in gastrectasia or in intestinal obstruction. When there is little or no chloride for the kidney to eliminate, nitrogen retention occurs, which leads to the phenomena of uremia. This condition should be suspected most especially when the urinary examination is practically negative excepting for the extremely low percentage of chloride in the urine. The blood chloride test (test 4) clinches the

differentiation. In normal individuals the blood chloride ranges between 450 and 500 mg per hundred cubic centimeters.

PROPHYLAXIS

The prevention of uremia is one of the chief indications in the therapy of nephritis (q v). It must suffice here to say that the most successful therapy of uremia lies in the recognition of the danger of uremic coma and in energetic efforts to jugulate it.

When the nephritic patient commences to complain of progressive weakness, sleepiness, headache or itching, and he is found to be mentally dull, with urinary odor of the breath and possibly incrustations of urea on his skin, most especially "urea frost" about the nostrils, a phenolsulphonphthalein test (test 5) at least should be taken. If the output is below 40 in the hour, the residual nitrogen in the serum is presumably increased. Special attention should be paid to the circulation, and myocardial insufficiency (q v) must be antagonized, for uremia is aggravated by heart weakness, which in turn increases with the production of a vicious circle.

The physician should beware of unduly antagonizing symptoms that might be interpreted as efforts at vicarious elimination. Diarrhea, vomiting, epistaxis or hemorrhoidal bleeding, if not excessive, may be salutary. If they seem to become too troublesome or to weaken the patient, they should be checked in a gradual rather than a sudden manner by the use of the remedies described elsewhere in connection with the therapy of these conditions. Against the gastro-intestinal manifestations of uremia, lavage of the stomach and bowel is likely to be the most efficient and least harmful procedure.

PREVENTION OF UREMIC COMA

The prevention of uremic coma in a patient threatened with it as suggested by the clinical phenomena described requires the following measures:

1 The patient should have absolute rest in bed.

2 The dietary regimen to be resorted to demands differentiation between at least four possible varieties of uremia: (a) intestinal intoxication predominating (indican and phenol in serum), (b) acidosis prominent, (c) hypochloridosis, (d) hypohydration.

(a) Starvation for a day is a good beginning when intestinal intoxication predominates, provided the patient is well nourished. This is followed by high carbohydrate-low protein diet (see Nephritis).

(b) Acidosis does not permit starvation. It demands a sugar diet from the start, which may consist, for example, of the juice of one lemon, one teaspoonful of cane sugar, and six tablespoonfuls of lactose in enough water for solution (1½ cupfuls). This quantity, given four times daily, yields 1,242 calories, which may suffice for possibly two days. It might be followed by the banana-cream diet: morning and evening 300 Gm of ripe bananas and 100 cc of cream, and at noon 200 cc of cream soup, 300 Gm of bananas and 200 cc of milk, yielding 1,335 calories, protein 29 Gm and alkali ash. This must not be continued for more than a few days and it should be followed by the lactovegetarian diet (see Nephritis) with an abundance of potatoes because of their alkaline ash. Protein must be but moderately restricted for continued sustenance.

Patients who are nearly always on the verge of uremia may be kept in a fair degree of comfort for a long time by a more or less weekly repetition of this program.

c) Hypochloridosis requires the additional administration of sodium chloride given if the stomach is retentive, in the form of retention enemas, hypophosphatosis or intravenous injection of Physiologic Solution of Sodium Chloride in accordance with the degree of the emergency. If this is extreme even hypertonic (10 per cent) salt solution may be used in phlebotomy, drop by drop. Great salt restriction is not feasible in any patient threatened with uremia.

d) Hypohydration is especially threatened when acidosis predominates. Such vomiting indicates gastric stasis. Give with 2 per cent sodium bicarbonate solution followed by duodenal tube administration of 1 or 2 cups of hot water (110 F) or of 2 per cent sodium bicarbonate solution (if acidosis is present) or of Physiologic Solution of Sodium Chloride if hypochloridosis prevails. Giving these solutions hot may be helpful in establishing profuse and salutary sweating.

The necessity for intestinal evacuation is especially demonstrated by the presence of indican and of phenol in the serum.

Mild Mercurous Chloride Tablets

Ten tablets of Mild Mercurous Chloride each 0.006 Gm.
Dose: One every hour until all are taken.

a) If constipation prevails, a saline cathartic, such as Sodium Sulphate (15 Gm.), may be given every morning, with possibly initial Mild Mercurous Chloride administration in broken dosage for the first day or two.

Magnesium salts are contraindicated in uremia owing to retention of magnesium ions in the system. Retention of coma—easily mistaken for uremic coma—may be induced in nephritic patients by magnesium sulphate purgation. It is not advisable to maintain a diarrheal condition by means of purgation, as this weakens the patient, because relatively more nutrient elements than nitrogenous waste products are lost in the watery stools.

b) When there is diarrhea, and also in the presence of constipation, prolonged colon irrigation with hot 2 per cent sodium bicarbonate solution is desirable, with the use of 2 or 3 gallons of the fluid in the course of 24 hours or two days.

Heat must be employed the more cautiously, the more critical the condition. Excepting for applications to the loins it is contraindicated by myocardial insufficiency. One may choose from among the following methods:

a) The loin poultice or hot wet pack is desirable, moist heat being better than dry heat in those cases in which the skin is harsh and dry.

b) The electric light "baker," either general or applied only to the loins, if the heart is weak, is the more convenient method. It is to be preferred therefore, provided the skin is tolerably active.

General diaphoresis by any one of these measures must not be attempted until improvement has commenced to set in, for fear of weakening the heart or of increasing hypohydration or hypochloridosis, thus aggravating the uremia. When definite improvement has set in, a mild degree of sweating may be salutary. Exhausting and drenching sweats should be avoided. The skin is but a poor vicarious emunctory for the uremic toxins. Pilocarpine Nitrate (5 mg. hypodermically or 15 mg. by mouth) is admissible only if the patient, while in a general heating procedure, does not sweat and has become extremely hot and uncomfortable. It is contraindicated by heart weakness and pulmonary

edema. Excessive or dangerous pilocarpine action may be promptly checked by Atropine Sulphate (0.5 mg.) given hypodermically.

5 Diuresis is contraindicated until considerable improvement has set in. Then it may be attempted cautiously, as discussed under "Therapy of Nephritis," with continued observation of the effect. The diuretic least likely to be harmful is water, which might be given as a deliberate "water thrust" of 2 or 3 liters of water or of other fluid daily, a careful watch being made of the effect on the urine and the intake being promptly diminished if the quantity of urine is not increased or as soon as the initial diuresis commences to fall off.

TREATMENT OF UREMIC COMA

The obstinate recurrence of the precoma manifestations or the actual development of true uremic coma is tantamount to the recognition of an incurably malignant condition and requires the application of the principles of the therapy of a hopeless case. When the patient is obviously moribund it is nothing less than cruel to subject him to a barrage of useless and disturbing procedures. It is one's duty then to practice euthanasia, i.e., to minimize, as far as possible, the agony of dying. When the condition is not as extreme, one should aim to prolong life as far as possible by gentle means but not at the expense of subjecting the patient, suffering from an incurable condition that will soon end his life, to painful or terrifying attempts at treatment that cannot do more than merely prolong his suffering for a while. True therapy is tender; it never tortures. It is the business of the physician to make the patient as comfortable and as cheerful as possible. When he asks whether there is any chance for him, the answer might be "The condition is serious but as long as there is life there is hope." To the patient's relatives the full gravity of the situation should be tactfully revealed. It is well to request a consultation, even if—and actually because—the diagnosis and prognosis are clear.

1 When, in spite of the application of the prophylactic measures discussed, the patient's condition becomes alarming or coma manifests itself suddenly, the immediate abstraction of 400 or 500 cc. of blood by vein puncture may be of telling effect. It might be repeated, if required, after four or five days, provided the hemoglobin percentage is not too low. Unfortunately, the results of subsequent abstractions of blood become progressively less satisfactory so that, while it should not be postponed too long, it also should not be resorted to unless actually required possibly to prolong life for a while. Blood transfusion is not to be recommended.

2 Lumbar puncture might be tried in cases that do not respond to other measures. It is stated to be of special value against the itching of uremia.

3 Dextrose phlebotomy might be employed in conjunction with bloodletting.

a) One might infuse 500 cc. of 5 per cent dextrose solution (without sodium chloride, unless there is hypochloridosis), and this might be repeated at intervals after the effect has been carefully observed. Continuous phlebotomy is contraindicated, as it would soon overburden the system with fluid.

b) When the heart is enfeebled or there is evidence of high intracranial tension one should preferably infuse from 100 to 200 cc. of 25 per cent solution of dextrose which might be repeated at intervals if the effect is satisfactory.

4 A heart stimulant, e g, strophanthin (from $\frac{1}{2}$ to $\frac{1}{2}$ mg) might be infused with the dextrose solution or injected intramuscularly, provided the patient has not been previously digitalized

5 A purgative might be resorted to if the patient's bowels are constipated

(a) Placing a drop of Croton Oil mixed with a little butter on the back of the patient's tongue is a time-honored procedure in the treatment of uremic coma

(b) Others advise that, because it is less drastic 0.6 Gm of Mild Mercurous Chloride with a teaspoonful of snow-ice be placed on the back of the tongue

(c) Compound Jalap Powder (from 2 to 4 Gm) in water might be given instead of either of the foregoing if the patient can swallow

6 The diet is not of primary importance at this stage The time has passed when rigid dietary restriction will do the patient much good His likes and dislikes should now be consulted

7 Of sedatives, (a) Morphine Sulphate is the physician's indispensable ally for the relief of symptoms that do not respond readily to simpler remedies It should be used against persistent hiccup, paroxysmal dyspnea (uremic asthma), muscle cramps, restlessness, insomnia and delirium In view of its presumably poor elimination in these cases, it should be given in moderate doses (from 8 to 16 mg) at intervals of perhaps six to eight hours It should be avoided, if possible, when there is itching, as it may aggravate the pruritus as an after effect It should be employed only as a last resort in the presence of Cheyne-Stokes breathing, as it greatly accentuates this disturbance

(b) Other sedatives may have to be resorted to when morphine is contraindicated, e g, bromide chloral or scopolamine (see Insomnia)

8 Of stimulants, (a) hot black coffee by mouth or rectum, or caffeine sodiobenzoate (0.2 Gm in ampule) given hypodermically may be of value in the dyspnea of Cheyne-Stokes respiration

(b) Atropine Sulphate (0.5 mg) might be tried against this dyspnea and it should certainly be given with the morphine, if the help of this remedy of despair is required

9 Surgery is contraindicated in the presence of uremia with the exception of the acute uremia of post-scarlatinal glomerulonephritis, in which kidney decapsulation may be worth trying In the uremia of prostatic hypertrophy, operation should not be undertaken until the blood has been rendered as nearly normal as possible

10 Complications, such as "renal pericarditis" and acute infections, should be particularly looked for in these cases When present, they are prone to be "terminal" and appropriate arrangements should be made, such as notifying distant relatives or, with Catholics, calling the priest

TESTS

TEST 1—*Blood Indicator*—1 Whole blood in centrifuge tube (about 10 cc) is allowed to coagulate Centrifuge decant obtaining 5 cc serum

2 To 5 cc of serum add an equal amount of distilled water (5 cc.)

3 Add 10 cc of 20 per cent trichloroacetic acid Filter

4 To filtrate, add a few drops of thymol reagent (5 per cent thymol in 95 per cent alcohol)

5 Add also to filtrate an equal amount of Obermayer's reagent (0.5 per cent ferric chloride in concentrated hydrochloric acid) Mix thoroughly Let stand two hours

6 Add 5 cc of chloroform, shake vigorously and allow to settle Read as 1 to 4 plus in settled chloroform according to depth of violet color

TEST 2—*Blood Phenol*—1 Obtain about 10 cc. of whole blood in a centrifuge tube, allow to coagulate, centrifuge and decant the blood serum

2 To 4 or 5 cc. of blood serum, add an equal amount of 20 per cent Trichloroacetic Acid

3 Filter

4 To 2 cc of filtrate, add 0.5 cc of concentrated nitric acid

5 Boil from half a minute to a minute.

6 Cool Add 1.5 cc of 33 per cent sodium hydroxide.

Reactions Positive a markedly golden color, depending on the degree of renal insufficiency Negative, a straw color

(Becher in 1924 used 0.03874 per cent aqueous solution of potassium bichromate as a standard, by means of a colorimeter) The gross reaction as described is sufficiently reliable

TEST 3—*Approximate Estimation of Chlorides in the Urine*—Apparatus required 1 A test tube. 2 Two medicine droppers of identical bore at the end 3 A 2.9 per cent solution of silver nitrate 4 A 20 per cent solution of potassium chromate

Technic 1 Put exactly 10 drops of urine in a test tube.

2 Add 1 drop of the potassium chromate solution. The fluid will now assume a somewhat distinctly yellow color

3 Add drop by drop, with a dropper of the same caliber, the silver nitrate solution until a permanent and distinct color change to red brown occurs (due to the formation of silver chromate)

The number of drops required to produce the change of color expresses in grams the content of chlorides per liter of urine

TEST 4—*Blood Chloride Test*—1 To 12 cc. of distilled water in a 20 to 25 cc. centrifuge tube is added 3 cc. of whole blood and then about 0.5 Gm of dry trimorphophenol The mixture is now stirred until protein precipitation is complete and the mixture turns a bright yellow color The precipitate is next thrown down in the centrifuge and the supernatant fluid is filtered into a dry tube

2 Five cc of the filtrate is then pipetted into a centrifuge tube of 25 cc capacity and 20 cc of the standard silver nitrate-acidified ferric alum indicator solution¹ added The contents are stirred to insure thorough mixing and the silver chloride precipitate thrown down in the centrifuge. The clear supernatant fluid is decanted into a clean dry beaker and 20 cc pipetted into a small porcelain evaporating dish for titration

3 The titration is made with ammonium thiocyanate solution² of such strength that 1 cc is the equivalent of 1 cc. of the silver indicator solution The end point is definite and consists of the first permanent tinge of reddish brown that extends throughout the mixture.

4 The calculation may be carried out with the aid of the following formula

$20 - (\text{titer} \times 5/4) \times 0.5 \times 100 = \text{mg of sodium chloride in 100 cc. of whole blood or plasma}$

TEST 5—*Phenolsulphonphthalein Test*—The patient, having received 400 cc of water, should empty the bladder completely An intramuscular injection is given of exactly 1 cc. of the dye solution

Exactly one hour and ten minutes after the dye injection, the patient should empty the bladder ("first hour" specimen)

Exactly two hours and ten minutes after the dye injection, the patient again empties the bladder ("second hour" specimen)

In the presence of edema, the dye must be injected intravenously

1 The standard silver nitrate-acidified ferric alum indicator solution may be prepared by dissolving 2.904 Gm. of silver nitrate in distilled water and making up to 1,000 cc and then mixing with 1,000 cc. of acidified indicator containing 100 Gm. of crystalline ferric ammonium sulphate and 100 cc of 25 per cent nitric acid Two cubic centimeters of this combined solution is the equivalent of 1 mg of sodium chloride Both the silver nitrate solution and the acidified indicator solution are one-tenth (combined one-twentieth) the strength of similar solutions employed in the Volhard Harvey method for urine.

2 The ammonium thiocyanate solution is standardized against the silver nitrate and made of equivalent strength It contains approximately 0.65 Gm of the thiocyanate to 1,000 cc. It is one-twentieth the strength employed for the Volhard Harvey method in urine

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

POLLEN EXTRACTS-U S STANDARD PRODUCTS CO—Solutions prepared by extracting the dried pollen of various species of plants with a buffered glycerosaline solution.

Actions and Uses—(See General Article Allergic Protein Preparations New and Nonofficial Remedies, 1934, p 25)

Dosage—(See General Article, Allergic Protein Preparations, New and Nonofficial Remedies 1934, p 25)

All of the pollen extracts-U S Standard Products Co are supplied in 5 cc vials containing 20,000 units per cubic centimeter. In addition, two of the products (Grasses Combined and Ragweed Combined) are marketed in single treatment set packages of three vials, containing respectively 100, 1,000 and 10,000 units per cubic centimeter and accompanied by a vial containing 2 cc of epinephrine hydrochloride solution 1:1,000.

Prepared by the United States Standard Products Company, Woodworth, Wis. No U S patent or trademark.

Prepared by extracting the dried pollen with a menstruum containing 67 per cent glycerin and 33 per cent of a physiologic saline solution containing 0.0908 per cent potassium dihydrogen phosphate and 0.238 per cent dibasic sodium phosphate. The pollen is extracted for twenty-two hours in a ball mill pulped and clarified by Berkeley filtration. The finished liquid is a 3 per cent extract of dried pollen. Each cubic centimeter represents 30,000 pollen units, one pollen unit being the equivalent of 0.001 mg of dried pollen. The marketed products represent appropriate dilutions of this stock solution and are preserved with 0.35 per cent of phenol.

SCARLET FEVER STREPTOCOCCUS TOXIN

(See New and Nonofficial Remedies, 1934 p 389)

Lederle Laboratories Inc Pearl River N Y

Scarlet Fever Streptococcus Immunizing Toxin—Prepared by the method of Drs. Dick under U S patent 1,547,369 (July 28, 1925 expires 1942) by license of the Scarlet Fever Committee, Inc. Marketed in single immunization packages of five vials of toxin containing respectively 500, 2,000, 8,000, 25,000 and 80,000 skin test doses also marketed in ten immunization packages of six 10 cc vials of toxin containing respectively 500, 2,000, 8,000, 25,000, 80,000 and 80,000 skin test doses per cubic centimeter.

SCARLET FEVER IMMUNITY TEST

(See New and Nonofficial Remedies 1934 p 406)

Lederle Laboratories, Inc Pearl River N Y

Scarlet Fever Streptococcus Toxin for the Dick Test—Prepared by the method of Drs. Dick under U S patent 1,547,369 (July 28, 1925 expires 1942) by license of the Scarlet Fever Committee, Inc. Marketed in packages of one vial containing sufficient toxin for ten tests in packages of one vial containing sufficient toxin for 100 tests.

AMINOACETIC ACID

(See THE JOURNAL, April 6 1935 p 1241)

Aminoacetic Acid-Calco—A brand of aminoacetic acid—N N R.

Manufactured by the Calco Chemical Co. Bound Brook, N J. No U S patent or trademark.

DIPHTHERIA TOXOID, ALUM PRECIPITATED (REFINED)

(See New and Nonofficial Remedies, 1934, p 393)

The Cutter Laboratory, Berkeley, Calif

Diphtheria Toxoid Alum Precipitated Refined—Prepared from diphtheria toxin having an L+ dose of 0.20 cc or less. The toxin is treated with from 0.3 to 0.4 per cent formaldehyde at a temperature of from 38 to 40 C until the toxicity is so reduced that the injection of five human doses into a guinea pig will produce no symptoms of local or general diphtheria poisoning. The toxoid is precipitated by the addition of not more than 2 per cent of potassium aluminum sulphate. The precipitate is washed twice with physiologic solution of sodium chloride and resuspended in physiologic solution of sodium chloride to a volume not less than the volume of the original toxoid. Merthiolate 1:7,500 is added as a preservative. The product is tested for potency according to the method prescribed by the National Institute of Health: guinea pigs weighing 500 Gm given one human dose, must develop within six weeks at least two units of diphtheria antitoxin per cubic centimeter of blood serum. Marketed in packages of 1 cc (one immunizing treatment) and in packages of one 10 cc vial (ten immunizing treatments).

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
RAYMOND HERTWIG Secretary

NOT ACCEPTABLE

DINA-MITE (BLUE LABEL) WHEAT BASE WHEAT—BRAN—FLAX

DINA MITE (RED LABEL) OAT BASE OATS—BRAN—FLAX

The Dina-Mite Food Company of Los Angeles submitted to the Committee on Foods a mixture of cracked hard and soft wheats, wheat bran and partially defatted flaxseed meal called "Dina-Mite (Blue Label) Wheat Base Wheat—Bran—Flax" and a mixture of rolled oats, wheat bran and partially defatted flaxseed meal called "Dina-Mite (Red Label) Oat Base Oats—Bran—Flax."

Analyses (submitted by manufacturer) —

Dina-Mite (Blue Label) Wheat Base	per cent
Moisture	9.0
Ash	3.2
Fat (ether extraction method)	2.5
Protein (N x 6.25)	11.4
Crude fiber	5.8
Carbohydrates other than crude fiber (by difference)	68.1

Dina-Mite (Red Label) Oat Base	per cent
Moisture	9.0
Ash	3.0
Fat (ether extraction method)	4.8
Protein (N x 6.25)	15.5
Crude fiber	5.0
Carbohydrates other than crude fiber (by difference)	62.7

Discussion of Name, Label and Advertising—The labels carry the statements "Wheat—Bran—Flax" and "Oats—Bran—Flax." Natural laxative food for young and old. With all their vital elements, protein, bulk and minerals. Dina-Mite used daily gives the system the proteins-heating-foods roughage bulk and minerals.

The name Dina-Mite for a laxative food is vulgar. The label statement listing food ingredients is incorrect, as partially defatted flax, and not 'flax,' is an ingredient. The indigestible roughage of these two products will increase the bulk of the intestinal contents but thereby tend to prevent only dietary constipation due to insufficient food residue. Constipation, however, may be due to many other causes. The label should correctly inform the consumer on these matters by recommending the foods for correcting constipation due only to insufficient bulk and advising that a physician should be consulted for cases not corrected in this simple manner. Bran and other foods providing considerable bulk may be irritating to sensitive bowels. Food high in bran content, if generally used by the aged, may be harmful. The products do not furnish all required proteins, food energy or minerals as stated or implied.

Some misinformative claims from the advertising follow:

A Healthy Body Means a Healthy Mind! Give your child a chance. A dish of Dina-Mite the famous Laxative Cereal bestows the energy and pep that school work requires. Relieves constipation.

A scientifically balanced natural food. Leading doctors endorse Dina Mite. Hospitals health centers maternity homes state custodial schools and other prominent state and private institutions, use and endorse Dina Mite. The Perfect Balanced Food. The famous health cereal health giving healthful for children. Health for your Kiddies. If you are a victim of constipation eat Dina Mite twice daily until the condition improves. It contains the essential elements for proper nourishment. Dina Mite is scientifically prepared to enable you to enjoy natural digestion and action. It is an important aid to great health. The wheat (ingredient) retains all of its vitamins proteins minerals and other vital elements. The bran added in scientific proportions gives additional roughage. Flax meal a wonder ful laxative specially treated and deodorized is the third ingredient and it is added in a healthful amount to stimulate normal bowel action.

The advertising includes testimonials of a therapeutic character for example

Dina Mite Food Co of Calif
Gentlemen

I am now on my third package of 1½ lb size Dina Mite (wheat). I have been troubled with chronic constipation for thirty years and have used laxatives perhaps every day during that period. Such a condition brought on stomach trouble that almost broke my health. I have lost twenty pounds during the past three years. I follow your cooking directions and eat the full portion with cream. After the second day I experienced immediate relief from constipation and gas pains which continues to improve. I have not taken medicine of any form lately. It is the first time for many months that I have been able to sleep without the use of a heating pad on my stomach or getting up at night to walk the floor for a couple of hours. I have gained four pounds in twelve days. I believe you really have struck oil.

(name given)

Dina Mite Food Co of Calif
Gentlemen

Hollywood California

I am very glad that you familiarized me with your special made food Dina Mite, when I last visited you. If more men and women would use your Dina Mite regularly they would need purchase less medicine and make fewer calls on the physician. It seems to have everything that such a food could or should have. Its mild laxative effect together with it having all the vital food elements makes it a very necessary food.

Very truly yours
(name given)

These foods will not 'bestow the energy and pep that school work requires'. The terms 'energy and pep' popularly imply a body condition of extreme well being or health which cannot be "bestowed" by any one food or even by the entire diet. The foods are not 'scientifically balanced as claimed. Statements of this character have no real meaning but because of vagueness are misleading by incorrectly implying that the products have unusual values by scientific test. They are not 'natural foods' but rather prepared foods and are not endorsed by "doctors hospitals, health centers, maternity homes, state and private institutions" as claimed. Vague claims of endorsement of this character falsely imply unique nutritional or therapeutic values, or that these professions or institutions as bodies have specially investigated and passed scientific judgment on the products, which is not true. These foods are not "perfectly balanced" but, rather to the contrary are deficient in many respects. They are not 'health cereals health giving or healthful for children' nor are they "health for your kiddies". No foods possess values warranting these designations. Health depends on many factors and conditions other than individual foods or even the entire diet. The foods do not contain the essential elements for proper nourishment", they are in fact much limited in this respect. Dina-Mite is not "scientifically prepared to enable natural digestion". Good digestion and Dina-Mite are not related in any manner. The bran is not 'added in scientific proportion'. This is a misuse of the term 'scientific,' which has impressive connotations.

Testimonials such as the two quoted apparently come from individuals unqualified to express a scientific or authoritative opinion or judgment on the values of Dina-Mite for accomplishing the results claimed. The testimonials by implication give further support to the medicinal or therapeutic character of the advertising as a whole. Testimonials have value only when coming from persons qualified by training and experience to express an unbiased, scientific judgment on the subject.

The labels and advertising are grossly misinformative and false. Advertising for foods should be simply and correctly informative to the consumer. Advertising not filling these qualifications is harmful to the public and to the food industry. These products therefore, cannot be listed among the accepted foods of the Committee on Foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

WAUKESHA ROXO MINERAL SPRING WATER

Distributor—Waukesha Roxo Company, Milwaukee

Description—Bottled spring water of moderate mineral content practically free of micro organisms

Collection and Bottling—The housed flowing spring at Waukesha, Wis., is protected from surface water contamination by a concrete encasement to a depth of thirty feet. The water is pumped through a filter and an ultraviolet ray machine into glass lined storage tanks from which it flows into filling machines and is sealed in bottles.

All bottles are washed in a bottle washing machine. Used bottles are sprayed with a 10 per cent sulphuric acid solution to remove mineral deposit, soaked and sprayed with 3 per cent caustic soda solution at 120 F under 30 pounds pressure, and given four fresh water rinsings. All pipes and storage tanks are regularly treated with sodium hypochlorite solution. Periodic inspections are made by the city of Milwaukee health department and bacteriologic examinations are made each month.

Analysis (submitted by distributor)—

Sanitary Analysis	Parts per Million
Ammonia nitrogen	0.01

CELLU JUICE-PAK RED RASPBERRIES

PACKED IN UN-DILUTED JUICE WITHOUT ADDED SUGAR

Distributor—The Chicago Dietetic Supply House, Inc., Chicago

Packer—Eugene Fruit Growers Association, Eugene, Ore.

Description—Processed red raspberries packed in undiluted juice without added sugar

Manufacture—Ripe red raspberries are placed in small containers to prevent crushing, conveyed to the factory, graded according to size, inspected for removal of foreign material, spray washed and packed into cans. The cans are filled with undiluted juice expressed from other red raspberries, heated for five minutes, sealed, cooked in a continuously agitated cooker for a definite time and at a definite temperature, cooled and stored. Before shipment, the cans are inspected and labeled.

REPORTS OF OFFICERS

NOTE—At the 1925 session of the Association, the House of Delegates suggested that all reports of officers, committees, etc., and resolutions to be brought before the House, if available be published in advance of the session so as to permit careful consideration and discussion—Ed

REPORT OF THE SECRETARY

To the Members of the House of Delegates of the American Medical Association

The following report of the Secretary is respectfully submitted

MEMBERSHIP

The members of the American Medical Association are those members of constituent state and territorial medical associations whose names have been officially reported for enrolment by the secretaries of the constituent associations. On April 1 1935, the membership list contained the names of 99,536 members as compared with 98,041 on April 1, 1934. During the year ended April 1, 1935 the names of 1,725 deceased members were removed from the membership list.

FELLOWSHIP

The number of Fellows of the Association as shown by the official roster on April 1, 1935 was 61,406, a gain of 692. During the year, 3,833 names were removed from the Fellowship roster, while 4,575 new names were added. Of the names removed 767 were those of deceased Fellows and 863 were the names of Fellows who had become ineligible for various reasons, while the names of 1,130 Fellows were removed because of failure to pay dues and 1,123 because of resignations.

An accompanying table shows the number of counties in each state and territory, the number of component societies as shown by the records in the Secretary's office, the number of members enrolled at the time the count was made for the purpose of compiling the table, and the number of Fellows including Honorary Fellows and commissioned officers of government medical services.

OFFICIAL CONTACTS WITH COMPONENT AND CONSTITUENT SOCIETIES

The number of visits made by members of the official personnel of the Association to component and constituent societies and the attendance at meetings before which the Association's representatives have appeared have been much larger during the past year than in any similar preceding period.

At the Annual Conference of Secretaries of Constituent State Medical Associations held in Chicago in September 1934 nearly every state association was represented by its secretary and editor, and a number of the presidents and other officers of state associations were present.

The President, the President-Elect, individual members of the Board of Trustees, the Editor, the Secretary and the directing heads of the Association's councils and bureaus have appeared on invitation, at the meetings of a large number of constituent state medical associations and component county medical societies. Many of them have addressed lay audiences in various parts of the country and have thus had opportunity to present the policies and the official point of view of the organized medical profession in the United States to a large element of the public.

BETTER ORGANIZATION

Marked progress has been made during the past year in increasing the efficiency of medical organization in a number of states and in many individual counties. There can be no question that the official machinery of the constituent state medical associations is being gradually and constantly improved. It has been extremely gratifying to note the increased interest and efficiency of the Councils of a considerable number of the state associations and the great improvement that has been made in working efficiency of a large number of county societies. The elected and appointed officers and committees of state

medical associations and of many county medical societies have rendered most devoted and efficient service in dealing with the many new problems that have been created through social

and economic changes within the last few years. Two additional constituent state medical associations have employed full time secretaries.

COMMUNICATIONS AND RESOLUTIONS

The following resolutions were received by the Secretary from the secretary of the California Medical Association

WHEREAS, Because the large area and the long distances of the constituent states on the Pacific Coast make it practically impossible for one trustee to maintain intimate contact with the medical organizations of these states and

WHEREAS For similar reasons one trustee is unable to visit these several states and advise them in regard to Association policies and activities and

WHEREAS Such intimate affiliations would enhance the work of the American Medical Association and also that of the state association therefore be it

Resolved That the Reference Committee on Amendments to the Constitution and By Laws prepare the following amendment to article 6 section 1 of the Constitution Strike out the word nine and insert therefor the word eleven thereby increasing the number of Trustees from nine to eleven and be it

Resolved That the House of Delegates adopt the rule that one trustee shall be elected from the Fellows in California and one from the mid west or southwestern part of the country

The Secretary received from the secretary of the National Society for the Advancement of Gastroenterology a communication enclosing resolutions as follows

WHEREAS The members of the National Society for the Advancement of Gastroenterology assembled Feb 6 1935 which organization is committed to the advancement of gastro-enterology for the benefit of American medicine and

WHEREAS Since the establishment of the Section on Gastro Enterology and Proctology in the American Medical Association eighteen years ago has done much in stimulating a higher quality of diagnostic and medical abdominal work in the profession in this country and

WHEREAS Most of the advances made have been accomplished by those who have been working intensively in this field of work and freely given of their advances to American medicine and

WHEREAS the members of this organization are all of them members of the American Medical Association in good standing be it

Resolved That we respectfully request our parent organization the American Medical Association to certify this field of work by authorization of the American Board of Gastroenterology to stimulate still better work in the subject on the part of the profession and request also that we as a national organization be given representation on the Board of Gastroenterology with the section of the American Medical Association and the American Gastroenterological Association

CALLED SESSION OF THE HOUSE OF DELEGATES

At the request of the Board of Trustees a special session of the House of Delegates called by the Speaker was convened Feb 15 and 16, 1935, in Chicago. Of a possible 168 delegates from the continental United States, 162 official representatives of constituent state medical associations, sections of the Scientific Assembly and government medical services were in attendance.

The following report of a reference committee appointed by the Speaker was unanimously adopted by the House of Delegates

Your reference committee believing that regimentation of the medical profession and lay control of medical practice will be fatal to medical progress and inevitably lower the quality of medical service now available to the American people condemns unreservedly all propaganda, legislation or political manipulation leading to these ends

Your reference committee has given careful consideration to the record by the Board of Trustees of the previous actions of this House of Delegates concerning sickness insurance and organized medical care and to the account of the measures taken by the Board of Trustees and the officials of the Association to present this point of view to the government and to the people

The American Medical Association, embracing in its membership some 100,000 of the physicians of the United States, is by far the largest medical organization in this country. The House of Delegates would point out that the American Medical Association is the only medical organization open to all reputable physicians and established on truly democratic principles, and that this House of Delegates, as constituted, is the only body truly representative of the medical profession

The House of Delegates commends the Board of Trustees and the officers of the Association for their efforts in presenting correctly, maintaining and promoting the policies and principles, heretofore established by this body

The primary considerations of the physicians constituting the American Medical Association are the welfare of the people, the preservation of their health and their care in sickness the

advancement of medical science, the improvement of medical care, and the provision of adequate medical service to all the people. These physicians are the only body in the United States qualified by experience and training to guide and suitably control plans for the provision of medical care. The fact that the quality of medical service to the people of the United States today is better than that of any other country in the world is evidence of the extent to which the American medical profession has fulfilled its obligations

The House of Delegates of the American Medical Association reaffirms its opposition to all forms of compulsory sickness insurance whether administered by the federal government, the governments of the individual states or by any individual industry, community or similar body. It reaffirms also its encouragement to local medical organizations to establish plans for the provision of adequate medical service for all of the people adjusted to present economic conditions, by voluntary budgeting to meet the costs of illness

The medical profession has given of its utmost to the American people not only in this but in every previous emergency. It has never required compulsion but has always volunteered its services in anticipation of their need

The Committee on Economic Security, appointed by the President of the United States, presented in a preliminary report to Congress on January 17 eleven principles which that committee considered fundamental to a proposed plan of compulsory health insurance. The House of Delegates is glad to recognize that some of the fundamental considerations for an adequate reliable and safe medical service established by the medical profession through years of experience in medical practice are found by the committee to be essential to its own plans.

However, so many inconsistencies and incompatibilities are apparent in the report of the President's Committee on Economic Security thus far presented that many more facts and details are necessary for a proper consideration.

The House of Delegates recognizes the necessity under conditions of emergency for federal aid in meeting basic needs of the indigent, it deprecates, however, any provision whereby federal subsidies for medical services are administered and controlled by a lay bureau. While the desirability of adequate medical service for crippled children and for the preservation of child and maternal health is beyond question, the House of Delegates deplores and protests those sections of the Wagner bill which place in the Children's Bureau of the Department of Labor the responsibility for the administration of funds for these purposes

The House of Delegates condemns as pernicious that section of the Wagner bill which creates a social insurance board with out specification of the character of its personnel to administer functions essentially medical in character and demanding technical knowledge not available to those without medical training

The so-called Epstein bill proposed by the American Association for Social Security now being promoted with propaganda in the individual states, is a vicious deceptive, dangerous and demoralizing measure. An analysis of this proposed law has been published by the American Medical Association. It introduces such hazardous principles as multiple taxation, inordinate costs, extravagant administration and an inevitable trend toward social and financial bankruptcy

The Committee has studied this matter from a broad standpoint, considering many plans submitted by the Bureau of Medical Economics as well as those conveyed in resolutions from the floor of the House of Delegates. It reiterates the fact that there is no model plan which is a cure all for the social ills any more than there is a panacea for the physical ills that affect mankind. There are now more than 150 plans for medical service undergoing study and trial in various communities in the United States. Your Bureau of Medical Economics has studied these plans and is now ready and willing to advise medical societies in the creation and operation of such plans. The plans developed by the Bureau of Medical Economics will serve the people of the community in the prevention of disease, the maintenance of health and with curative care in illness. They must at the same time meet apparent economic factors and protect the public welfare by safeguarding to the medical profession the functions of control of medical standards and the continued advancement of medical educational requirements

They must not destroy that initiative which is vital to the highest type of medical service

In the establishment of all such plans, county medical societies must be guided by the ten fundamental principles adopted by this House of Delegates at the annual session in June 1934. The House of Delegates would again emphasize particularly the necessity for separate provision for hospital facilities and the physician's services. Payment for medical service, whether by prepayment plans, instalment purchase or so called voluntary hospital insurance plans, must hold, as absolutely distinct, remuneration for hospital care on the one hand and the individual, personal, scientific ministrations of the physician on the other.

Your reference committee suggests that the Board of Trustees request the Bureau of Medical Economics to study further the plans now existing and such as may develop with special reference to the way in which they meet the needs of their communities, to the costs of operation to the quality of service rendered, to the effects of such service on the medical profession and to the applicability to rural, village, urban and industrial population, and to develop for presentation at the meeting of the American Medical Association in June model skeleton plans adapted to the needs of populations of various types.

Harry H. Wilson, Chairman, California
Warren F. Draper, Virginia
E. F. Cody, Massachusetts
E. H. Cary, Texas
N. B. Van Etten, New York
F. S. Crockett, Indiana
W. F. Braasch, Minnesota

A large number of component county medical societies in various parts of the United States have taken official action endorsing the report adopted by the House of Delegates at its called session. Speaking through their councils or through called meetings of their houses of delegates, several constituent state medical associations have taken similar action.

The Secretary makes grateful acknowledgment of the many courtesies and kindnesses extended to him by the officers and members of official bodies of the Association and of state associations and county societies, as well as by hundreds of individual members.

Respectfully submitted

OLIN WEST, Secretary

REPORT OF THE BOARD OF TRUSTEES

To the Members of the House of Delegates of the American Medical Association

The demands made on the various councils, bureaus and departments of the Association and the amount of business transacted by the Board of Trustees and other official bodies were far greater during the last year than in any previous year. At no time in the history of the Association have there been matters of more transcendent importance presented for official consideration and action at the hands of the various official bodies that carry on the work of the Association. In some instances, existing facilities in the Association's offices have been taxed to the utmost and the situation has been one that has called for extreme exertion on the part of the administrative personnel and for well considered action on the part of the officers, councils, bureaus and members of official groups.

The Association has continued to comply to the fullest possible extent with the provisions of the National Recovery Act and with the pronouncements of the National Recovery Administration with respect to wages, working hours and all other phases of the Association's work on which the National Recovery Act has any bearing.

As will be seen from the Auditor's Report, total general operating expenses including depreciation amounted to the sum of \$825,781.09 for the year covered by this report as compared with \$836,954.04 in the preceding year. Association expenses including the cost of operation of councils, bureaus and departments and of miscellaneous operations were \$350,297.48 in 1934 as compared with \$333,730.40 in 1933. The increased expenditures in 1934 were occasioned by the expansion of the work of various councils and bureaus. Miscellaneous expenses

and losses in 1934, including building depreciation, amounted to \$139,084.96 as compared with \$212,961.40 in the preceding year. The reduction in expenditures included under miscellaneous expenses and losses was due to the saving in the amount of insurance and taxes paid, and in the amount required for legal services, as well as to the reduction of the sum charged against the Directory, which may be accounted for by the fact that there was little or no sale for copies of the Twelfth Edition of the Directory in 1933. There was also a marked reduction in the loss incurred through the publication of *HYGEIA*.

The total operating income for 1934 was \$1,439,751.07 as compared with \$1,375,337.99 for the previous year. Interest received from investments amounted to \$82,402.41 almost exactly \$5,000 more than income from this source in 1933.

Net income for the year was \$252,528.02 representing an increase of \$164,062.98 over the net income received in the preceding year. This difference is largely accounted for through increases in the amounts received from Fellowship dues and subscriptions to *THE JOURNAL*, and in income from advertising and from interest on investments, and through reduction in the costs involved in the publication of *HYGEIA* and in the costs charged against depreciation. During the year, an appraisal of the Association's property was made by the American Appraisal Company, and it was in accordance with the findings of this appraisal that the amount indicated was charged against depreciation. A large part of the increased income from dues and subscriptions came from the payment of accounts in arrears.

An appraisal of the bonds owned by the Association was made at the end of the year and disclosed that the total market value of these securities at that time was greater by the sum of \$66,627.13 than the total cost. The Board of Trustees has attempted to pursue a thoroughly conservative policy in the purchase of securities for investment. In a number of instances, premiums have been paid for bonds purchased in order that the securities held by the Association might be of the highest possible quality. Because of prevailing low money rates, the general tendency toward the reduction of interest rates and the high cost of desirable securities, it is quite probable that the amount of interest on securities that will be realized in the next few years will be considerably lower. This will be especially true with respect to income received from investments in government securities, which make up the larger part of the Association's investments. The government has, where possible, called for payment practically all of its bonds with interest rates in excess of 4 per cent and has replaced them with others having much lower interest rates.

During a part of the year it was necessary to employ extra help in connection with the publication of the American Medical Directory, and additional employees were needed for various periods of time in the printing department. Because of increased living costs it was necessary to restore the cut in wages and salaries that was made in 1933. At the end of the year 1934 the total number of employees in actual service was 518.

The Journal of the American Medical Association

THE JOURNAL continued during 1934 the developments begun in previous years. Today it is everywhere recognized as the leading medical publication of the world and as the official voice of the American medical profession. It has kept its readers abreast of developments in the field of legislation and it has spoken promptly for scientific medicine when the tenets and principles of the profession seemed about to be subjected to assault.

Not only from individuals and medical organizations in this country, but from all over the world come constantly appeals for the use of the facilities and prestige of *THE JOURNAL* in advancing various medical causes.

Several series of articles published during last year have attracted extraordinary support from readers. Attention should be called particularly, to a new series on the "Therapy of the Cook County Hospital" and to the special articles arising from the general sessions held as part of the annual session of the Association. The department devoted to questions and answers continues also to receive numerous letters of approval from readers of *THE JOURNAL*.

Tables 1 and 2 indicate the approximate count of Fellows and subscribers carried on the mailing list of THE JOURNAL, showing the gain or loss of Fellows and subscribers in each state, and the number of physicians receiving THE JOURNAL in each state

TABLE 1—Approximate Count of Fellows and Subscribers on The Journal Mailing List by States Dec 31, 1934, Also Gain or Loss in Each State

The number of copies of THE JOURNAL printed in 1934 was 4 456,970, while the average number of copies printed weekly was 85,711 The total number of Fellows and subscribers receiving THE JOURNAL, Dec. 31, 1934, was 85,535

Special Journals

During 1934 the special periodicals issued by the Association have continued to serve the advancement of medicine in highly technical fields The editors have cooperated in such stringent economies as seemed desirable, doing much to eliminate unnecessary illustrations, profuse tabular material, and verbiage not necessary for suitable understanding of the material presented

THE ARCHIVES OF INTERNAL MEDICINE initiated as a new feature a series of reviews in various fields in internal medicine

The Board of Trustees would again tender its appreciation to the editors who have given so fully of their time and effort for the maintenance of the high quality of these publications, and also to such institutions and individuals as have aided in the publication of special articles by bearing a portion of the cost of publication.

The total loss incurred in publication of the special journals for the year 1934 was \$14 936 44 The total circulation of these journals, Dec. 31 1934 was 19 384

The Quarterly Cumulative Index Medicus

THE QUARTERLY CUMULATIVE INDEX MEDICUS is the only publication of its kind in the world. The mass of detail, the tremendous number of periodicals regularly indexed, the necessity for accuracy, and the discrimination desirable in the selection of publications and titles for indexing make the task of issuing this publication a most difficult one It is doubtful that any other medical organization in the world, either public or private, could undertake successfully the issuance of this work The American Medical Association deserves special recognition for supplying the funds necessary and the facilities that are required to bring out this monumental contribution to medical bibliography

The Library

The package library service continues to provide physicians in communities throughout the United States with the latest available data on problems that concern them. During 1934, 2,816 packages were sent out, an increase of some 25 per cent over the number circulated in 1933 As in previous years, numerous letters of commendation have come to the headquarters office in appreciation of this service.

The packages are especially useful to physicians in small communities who do not have available opportunity for consultation in local libraries

TABLE 2—Physicians Receiving The Journal*

* This table gives the number of physicians (based on the Thirteenth Edition of the American Medical Directory) in the United States the number receiving THE JOURNAL and the approximate percentage in each state. Copies to physicians in the United States Army and Navy are not included

Similar medical package library services have been developed by a number of the state societies and by other organizations in the field. Nevertheless this subsidiary service has not as indicated in the increase for requests for this material diminished in any way the demands on the headquarters office for this educational activity

The periodical lending service, which supplements the package library service, lent 8333 periodicals to physicians who requested them. The periodicals regularly listed and abstracted in *THE JOURNAL*, and all those regularly received by the *QUARTERLY CUMULATIVE INDEX MEDICUS* are available for such service. This demand represents a 20 per cent increase over the circulation of periodicals in 1933.

The library of the Association also supplied reference service in response to 5,000 individual requests.

The employees' library had a circulation of 5510; the average daily circulation was 23, the number of borrowers 128.

Visitors from abroad who have seen the development of the package library and reference services of the American Medical Association are enthusiastic in their recognition of the qualities of this work, a type of service not duplicated either in scope or in minimal cost by any other organization.

Hygeia

HYGEIA is recognized today as the only rational publication printed to provide information to the public on matters of health that is interesting, authentic, attractive, and supported by leading organizations in the field of education and the public health. The editorial staff continually exerts itself to advance the quality of the material to new heights.

Series of articles on insects and other parasites of man, the care of the teeth, the hygiene of the eye, and many other topics have been quoted and republished in many places. Publishers of textbooks used in the schools, and leaders of various types write regularly for permission to include material from this magazine in such volumes, thus extending the educational quality of the periodical far beyond its immediate circulation.

A special effort has been made during 1934 to carry to the readers of *HYGEIA* the interests of the medical profession in matters of social security and medical economics. Reprints from its pages have been circulated through the Bureau of Medical Economics and in other ways.

Schools and libraries continue to represent a large percentage of the circulation of *HYGEIA*. Moreover, the use of the magazine for projects in study by pupils in grade and high schools indicates the extent to which the health interests of the future generation are being molded by this publication.

The net loss incurred through publication of *HYGEIA* for 1934 was \$2,059.55, as compared with the net loss of \$30,127.54 in 1933. Total receipts from subscribers exceeded the amount received from the same sources in the previous year by approximately \$30,000, while there was a reduction of a little more than \$5,000 in advertising income.

Since *HYGEIA* is published for the benefit of the lay public, it is perhaps natural that 81 per cent of the subscribers are laymen.

American Medical Directory

The Thirteenth Edition of the American Medical Directory was made available to subscribers, Aug. 7, 1934. The new volume contains the names of 178,516 physicians, including 18,727 new names. The names of 11,473 physicians who died during the interim since the publication of the Twelfth Edition of the Directory were removed and the number of those whose addresses were unknown has been reduced, so that the actual increase in the number of names was 6,167. The new Directory is larger by twenty-six pages than the volume previously published. The total cost of the new edition was greater by \$47,394.58 than that of the Twelfth Edition, largely because the publication of the new edition was delayed for twelve months by reason of the unfavorable economic situation. This delay naturally occasioned a tremendous number of changes in addresses, so that it was necessary to reset the type for the entire Directory. Sales receipts at the end of the year 1934 were less by the sum of \$33,934.28 than income received. It is hoped that a considerable part of this loss will be made up as sales proceed.

Cooperative Medical Advertising Bureau

The Cooperative Medical Advertising Bureau represents thirty-two journals of constituent state medical associations. The net earnings of the Bureau for 1934 were \$21,247.06 as compared with \$19,266.25 for 1933. Of the earnings of the

Bureau the sum of \$6,000 was remitted to the state journals concerned. This sum, \$1,000 more than was similarly remitted in the previous year, was distributed to the state journals concerned in proportion to the total amount of advertising secured for each of them.

Mailing and Order Department

During the year the Mailing Department handled 153 tons of mail in the third and fourth classes and in miscellaneous second class. This included the material distributed through orders received for pamphlets, booklets, reprints and so on, amounting to 284,777 units, the weekly mailing of *THE JOURNAL*, and the mailing of other publications. The number of orders received and handled through this department was 77,423.

Of first class mail, 475,937 pieces were transmitted, and of third class mail 1,564,684 pieces. In addition to the material distributed by mail, a large amount was shipped by express and by freight.

Council on Pharmacy and Chemistry

This report marks thirty years of service to the medical profession on the part of the Council on Pharmacy and Chemistry. The first session was held Feb. 11, 1905, and for nearly a third of a century the Council has made notable contributions for the furtherance of rational therapeutics. Its scope has extended to improved methods of teaching materia medica, to the evaluation of new drugs which the physician has been importuned to use to the education of the profession concerning newer advances in medicine, and to safeguarding public health by bringing forcibly to the attention of the profession, of the public and of legislative bodies the need for corrective measures.

Of the personnel of the Council, four members of the original group who attended the first meeting in Pittsburgh in 1905 still remain active members of the Council in 1934, another one of the original group, though no longer a member of the Council, still takes an interest in its work.

A comparison of conditions prevailing previous to 1905 and those of today reveals strikingly the progress that has been possible largely through the work of the Council. The Council is so busily engaged in the work which is before it that its members cannot devote time to making speeches before medical meetings or to other methods of bringing the work of the Council closer to the profession than through the columns of *THE JOURNAL*. It is to be regretted that there are some members of the profession who have not heeded the warning on the dangers of proprietary domination of therapeutics. The Board of Trustees recently passed a resolution expressing the hope that at meetings of medical societies, hospital staffs and various other conferences there will be emphasized the benefits which will be incurred by the profession in increasing measure if the profession will be still more attentive to the work of the Council. Physicians when asked to try a new remedy might well inquire whether it has been accepted by the Council on Pharmacy and Chemistry. Any honest manufacturer, small or large, can have his products considered by the Council. The Council is unique in that no remuneration whatever is accepted for its considerations and it is entirely free from any domination or advertising entanglements.

The work of the Council has expanded to an extent that has made it necessary to enlarge its office personnel. Within two years the amount of work has increased by 50 per cent. The reason for this is that the efforts of the Council are being recognized and appreciated more and more by physicians and this recognition is directly reflected in the desire of pharmaceutical houses of the better grade to obtain Council acceptance of their products. Each year finds it more difficult for the less progressive or less conscientious firms to sell drugs to the medical profession and particularly to institutions.

PUBLICATIONS OF THE COUNCIL

New and Nonofficial Remedies—This book maintains its leadership in the field of authoritative information on nonofficial drugs. During the past year approximately 6,300 copies of *New and Nonofficial Remedies* were distributed to students of materia medica and pharmacology in class A medical schools. The revisions of *N. N. R.* for the 1935 edition have been extensive but not nearly so extensive as will be next year's revision.

when the new Pharmacopeia becomes official. The 1935 volume contains many additions newly admitted in 1934, while older drugs have been omitted as recent advances have rendered them obsolete. The standards for vitamin A and D preparations have been considerably revised, based on the interim revision of the U. S. Pharmacopeia. The Council decided, however, that preparations included in N. N. R. must exceed by a certain amount the minimum requirements of the U. S. Pharmacopeia so far as vitamin A is concerned; the vitamin D content is the same. A special statement sent out on this subject has commanded wide attention. The consideration of antiseptics has been to the fore in the past year and much work has been done by the Council's referee on this subject in order that the status of products in N. N. R. may be further brought into harmony with the progressive scientific evidence dealing with bactericides and bacteriostatic agents. Biologic products also have demanded consideration, though relatively few of the newer preparations have been found worthy of admission to N. N. R. During the year a number of interesting new drugs were accepted. Among these were Carbarsone, an arsenical used chiefly in the treatment of amebiasis (the Council published a special report on this drug supplementing the preliminary report of 1932), Hippuran and Diodrast, two different types of urographic contrast mediums. Carotene, the precursor of vitamin A. Dilaudid, a substitute for morphine, Neo-Synephrin Hydrochloride, which has a number of advantages as a vasoconstrictor over synephrin tartrate. Diothane, which represents a type of local anesthetic entirely different chemically from any heretofore accepted for N. N. R., and Scillonin, an example of the development of a drug that was on the market as long as thirty years ago sold with claims that could not be countenanced by scientific medicine.

Reports of the Council—The Council has continued publishing adverse reports for the benefit of the medical profession. They were on such products as Oleothesin, Bismoid, Asthmolysin and Spasmolysin, Vita-Cell, Di-Hydranol, Iodochlorol, and Yeast Vitamin-Harris. These, however, represent but a small proportion of the number of adverse reports as many of the products not accepted were withdrawn from the market or were not sufficiently important to warrant publication of reports in THE JOURNAL. These will therefore appear in the Annual Reprint of the Reports of the Council on Pharmacy and Chemistry. Always on the agenda are products on which adverse reports have been made but which the Council has agreed not to publish if the manufacturer in turn agrees not to promote the sale of the product pending efforts to obtain further evidence for the consideration of the Council.

Among the more noteworthy special and preliminary reports published by the Council of a particularly informative nature was that on Phenylmercuric Nitrate (Basic), canvassing the work that has been done on this interesting substance, also the statement to the medical profession on the relation of amidopyrine and barbitol derivatives to granulocytopenia. Since the latter statement has been published, there seems to be a much better understanding on the part of the profession concerning the part played by these two drugs as possible causative factors in this disease. Another carefully considered special report was that on Sterility of Ampules, based on a thorough questionnaire sent to manufacturers. It seems quite likely that as a result of this report all manufacturers will soon be making and testing their products according to a uniform procedure, which will obviate practically all possibility of contamination. The Council published other preliminary reports on drugs the status of which was still somewhat doubtful. Among these were the reports on Pertussis Vaccine, Cystine Hydrochloride, Gastric Mucin and Anthralin.

'Useful Drugs'—'Useful Drugs' underwent a thorough revision during 1934, so that the content of the book is entirely up to date. A less extensive revision will be made in 1936 to bring it into harmony with the new issue of the Pharmacopeia so far as titles and collateral information are affected.

REVISION OF FOOD AND DRUG ACT

The Council through its special committee on proposed food and drug legislation gave careful attention during 1934 to the formation of a 'platform' expressing its position in regard to

drugs. This platform and also a similar one issued by the Committee on Foods was endorsed by the Board of Trustees and published in THE JOURNAL, Jan. 12, 1935, page 125.

SPECIAL INVESTIGATIONS

Special investigations are under way on *Bacillus Acidophilus* preparations, which have been in a somewhat unsettled state. Under the direction of the referee for these preparations an extensive examination of market specimens was made. As a result of this work, in conjunction with a careful study of the literature, the Council decided to retain *B. Acidophilus* Milk in N. N. R. On the other hand, examinations and evidence indicated that the promotion of these products in the form of blocks or non-milk-containing beverages was ill advised. Therefore reports on the omission of the latter type of products from N. N. R. were published.

The Council is about to issue a report on the sterility of thromboplastic substances, based on bacteriologic examinations of market specimens obtained from various cities in the United States.

USE OF NUMBERS IN NAMES

In last year's report there was discussed the decision of the Council concerning the removal of numbers from the names of drugs. This was done to prevent the confusion of numbers in prescribing. The Council is pleased to report that, in the case of all accepted products having numbers in connection with the name, the manufacturers, with one exception, agreed to omit the numbers.

The Council is being called on more and more to pass on names for new therapeutic products. The matter of naming a new preparation intended for therapeutic use is so involved that it seems necessary that there should be a central body for this consideration. In this capacity the Council has served a useful purpose. An example of the erroneous naming of products is the case of crystalline vitamin C. The chemistry of this product was worked out by Szent-Györgyi, so that it could be obtained in pure form and of a known composition. It was Györgyi's right to name the product, but unfortunately he chose the name "Ascorbic Acid." The name Ascorbic Acid is therapeutically suggestive, and though it is not as bad as some others for therapeutic products, it would be inconsistent of the Council to accept any therapeutically suggestive name. Therefore the Council was obliged to coin a new name for the product—Cevitamic Acid, which name has been adopted by American manufacturers. The firm, however, is permitted to use for one year the subtitle "Introduced as Ascorbic Acid."

SPECIAL ARTICLES

For many years bacteriophage preparations have kindled the imagination of workers in bacteriology. During this time there have been attempts by practically all pharmaceutical houses to place such products on the market. The therapeutic indications have never been clearly defined and the Council has not felt justified in accepting any bacteriophage preparation for inclusion in N. N. R. Because there was no well formulated statement on the evaluation of bacteriophage preparations, the Council asked one of its members, Dr. Stanhope Bayne Jones, to undertake the preparation of such a report. An excellent comprehensive "special article" by Drs. Monroe Eaton and Stanhope Bayne-Jones was published in three issues of THE JOURNAL in 1934. The contribution has been exceptionally well received.

Approximately ten years ago there was published under the auspices of the Council a series of articles on Glandular Therapy. This series was later reproduced in book form (two separate editions), the entire book comprising ninety-eight pages. The knowledge in this field grew so tremendously that in 1928 it was necessary to withdraw the book from circulation because it no longer covered the field adequately. The demand continued, and in 1934 the Council in cooperation with THE JOURNAL invited a number of prominent medical men to contribute articles to a series on Glandular Therapy. This series is by far the most extensive ever published under the auspices of the Council and is to appear during the current year. When completed it will be reproduced in book form containing more than 400 pages.

The Chemical Laboratory

The constantly growing work of the Council on Pharmacy and Chemistry and the complex nature of current problems with which the Chemical Laboratory must deal have resulted in imposing unusually heavy burdens on its personnel during the last two years. When a new product is submitted to the Laboratory, it is necessary to make careful investigations to determine its composition and structure. If it is found to be satisfactory from a chemical point of view and is accepted by the Council for inclusion in New and Nonofficial Remedies it is then necessary that suitable standards be elaborated. These standards are established with a view to insuring the highest possible purity in order that the public interest may be properly protected, and an effort is made to avoid creating undue hardships on producers.

Among the important new chemotherapeutic products submitted and studied during the year were Dilaudid, a narcotic somewhat similar to morphine, Diothane, a local anesthetic of a materially different type from any heretofore described in New and Nonofficial Remedies, and Larocaine, a local anesthetic. A great deal of careful investigation and laborious effort were required in preparing suitable standards for these products.

Carotene (provitamin A) was the first of the crystalline vitamin or vitamin like products examined by the Laboratory involving the use of absorption spectrum methods. In cooperation with the manufacturer, suitable standards were outlined. Another vitamin product, introduced abroad as ascorbic acid and now known in the United States under the nonproprietary term of *cevitamic acid*, was studied, and standards were elaborated. This product in pure form is crystalline vitamin C, and a description of the optical properties of the crystals is included in the standards.

Scillonin, a glucoside preparation from squill was further studied during the year and proper controls and standards for this preparation have been defined by the Laboratory and adopted by the Council on Pharmacy and Chemistry.

Two types of arsenicals have been under investigation. One of these is a new product, a purified form of arsenoxide, first described by Ehrlich but more recently subjected to an exhaustive therapeutic investigation. The other important arsenical for which standards have been elaborated is Carbarsone, recently accepted by the Council for inclusion in New and Nonofficial Remedies.

The investigation of barbital preparations has been continued because of the greatly increased use of these products and because a new barbital derivative has been added to the list each year during the last decade.

Vasoconstrictive substances have also required attention at the hands of the Laboratory staff, among these having been Neo Synephrin Hydrochloride, an ephedrine-like substance and ephedrine. The development of refinements in the manufacture of ephedrine and newly available knowledge concerning its chemistry have made it necessary for the Laboratory to reinvestigate this product with the idea of evolving standards that will be more in keeping with recent developments. Within the last year, another form of the ephedrine base has been brought out, the hemihydrate. The alkaloid may now be obtained either in the form of anhydrous ephedrine or in the form of hydrated ephedrine.

Certain new bismuth compounds have been investigated and continued attention has been given by the Laboratory to dextrose solutions and to solutions of invert sugar. Studies have also been undertaken, for the purpose of making proper revision of standards, on certain calcium compounds and other important therapeutic products, and a large number of other substances have been studied.

The Laboratory staff has continued its cooperation with various departments of the Association, and members of the staff have appeared at the meetings of several scientific organizations and have participated in their programs.

Council on Physical Therapy

There is undoubtedly a more general appreciation of the value of physical therapy methods in the treatment of disease and it is believed that the investigations and studies of the Council on Physical Therapy pertaining to the efficacy of heat

massage, exercise and other therapeutic agents are, to a considerable extent, responsible for the more general acceptance and application of physical therapy methods. The Council believes that physical therapy has a place in all branches of medicine and does not advocate that it be considered a distinct specialty. It believes that it is desirable that instruction in physical therapy should be incorporated in the courses of instruction in the broad field of therapeutics and that the subject should be properly taught in medical schools. The Council has therefore brought this matter to the attention of the Association of American Medical Colleges. The Council also believes that much can be done to extend knowledge concerning the value of physical therapy and to increase the practical application of physical agents through extension courses and to this end it has undertaken to develop a plan whereby the services of competent speakers may be made available to county and state medical societies.

During the year, seventy reports pertaining to submitted products were prepared, forty-seven of which indicated acceptances by the Council while twenty-three indicated rejections. Not all of the reports pertaining to rejected products were published, since some of them were held in abeyance pending improvement of the products or essential changes in the nature of advertising in order that these products might be made acceptable. Fifteen articles on newer methods of physical therapy were published during the year. The Council has prepared a statement setting forth its requirements with respect to the acceptance or rejection of abdominal belts, supports and similar devices, and it is planning to prepare a similar statement of requirements applying to shoes, posture appliances and other orthopedic devices. In the field of ultraviolet therapy considerable difficulty has been encountered, because no adequate dosage meter for determining the strength of ultraviolet radiation has heretofore been available. During the past year two reliable meters have been investigated and accepted by the Council. Investigations of ophthalmologic appliances have progressed in a fairly satisfactory manner, and reports pertaining to several such appliances have been published. The Council desires to make grateful acknowledgment of the aid received from the Committee on Standardization of Instruments and Drugs of the Section on Ophthalmology of the American Medical Association in connection with the appraisal of ophthalmologic devices. The Council has also continued its work in the investigation of aids to hearing and of instruments for diagnosing degrees of deafness. The consideration of radon and radium products has been continued, and studies of the physical characteristics and therapeutic efficacy of so-called short wave diathermy are now being carried out.

Bureau of Medical Economics

Interest and activities in the field of medical economics during 1934 were sharply focused on insurance as a method of providing medical and hospital care. For many years the medical profession has been aware of the sickness insurance systems of Europe. Even though all physicians in the United States have not been thoroughly conversant with every detail of foreign sickness insurance, the subject has on several occasions been given serious consideration by the House of Delegates.

Repeatedly that body has recorded its opposition to any form of state medicine or compulsory sickness insurance operated or controlled by the state.

The interest in and the efforts to develop insurance plans as a means of providing medical services or distributing their costs had been largely sporadic, or at most epidemic, until about two years ago when the Committee on the Costs of Medical Care in its Majority Report, recommended insurance as a means of equalizing the burden of the cost of medical care on low income groups.

Since the medical profession in general was not sufficiently impressed with the committee's Majority Report to accept its recommendations, certain interests and individuals outside the medical profession became the self-appointed champions of the sickness insurance cause in the United States. The persistent propaganda poured forth by these interests, represented by certain foundations is too well known to need detailed description here.

In order that the most recent authentic data might be available for the medical profession, the Board of Trustees directed that a study be made of sickness insurance abroad. This study, entitled "A Critical Analysis of Sickness Insurance," was completed and published in the April 1934 issue of the *AMERICAN MEDICAL ASSOCIATION BULLETIN*. Since that time more than 15,000 reprints of this report have been distributed to state and county medical societies, individual physicians and other interested groups and individuals.

In September 1934 the American Association for Social Security announced that a state sickness insurance bill prepared by that organization would be introduced in as many state legislatures as possible during the sessions beginning in January 1935. An analysis of this bill, which had one revision at the hands of the authors, appeared in the *AMERICAN MEDICAL ASSOCIATION BULLETIN* and reprints were sent to the secretaries of all state medical societies and many county medical societies. Requests for this analysis have been received from manufacturers' associations and many individual physicians.

Toward the autumn of 1934, the demand for information on sickness insurance was so great that other reports, discussions and reprints were prepared by the Bureau. Some of these reprint articles had previously appeared in the *AMERICAN MEDICAL ASSOCIATION BULLETIN*, and one had appeared in *HYGIEA*. It has been necessary to reprint these articles several times to supply the demand for them. The distribution given below is approximately correct.

	A M A Bulletin & Hygeia Distribution	Reprints
Critical Analysis of Sickness Insurance	60 000 plus	12 000
Sickness Insurance Catechism		30 000
Sickness Insurance not the Remedy (First published in the A M A Bulletin in June 1934)	60 000 plus	20 000
Health Insurance in England and County Medical Plans in the U S (First published in A M A Bulletin in October 1934)	60 000 plus	7 500
Sickness Insurance and Sickness Costs (First published in Hygeia in December 1934)	80 000	10 000
Handbook on Sickness Insurance, State Medicine and the Costs of Medical Care		2 000

To make it possible for the American Medical profession to have available authentic information on sickness insurance the Bureau of Medical Economics has assembled from all known sources and is continuing to collect documents, reports, articles, statistics and books on all phases of the sickness insurance question. This material is in several foreign languages as well as in English, some of it has been difficult to obtain, and but few of the documents are duplicated. Although the material is in use almost constantly, it is available to any member of the Association who desires to study the original documents in the office of the Bureau. Assistance will be given to those interested in such a study and the Bureau will be glad to find the references in which they are most interested. The Bureau will be especially glad to have visits by chairmen or members of medical economics committees.

The Handbook on Sickness Insurance was first printed in December 1930 to meet the demand on the part of high school and college students for source material with which to prepare debates on state medicine and sickness insurance. The book contained either entire articles or abstracts of arguments presented by well known authors both for and against state medicine and sickness insurance. During August and September 1934, this handbook was revised and rearranged with much new material added. It is now being used not only by high school and college students in preparing debates and theses but also by many physicians in preparing lectures and statements on the subjects covered in the handbook. This publication is a 182 page answer to the criticism sometimes heard, that the publications of the American Medical Association present only one side of the argument on state medicine and sickness insurance.

GROUP HOSPITALIZATION

Since 1931, group hospitalization has been spreading throughout most sections of the United States. At first group hospitalization was urged by commercial organizations whose interest in hospital care was secondary to the profits they could derive by promoting, organizing or conducting membership drives. Hospital administrators gradually shifted their

attention from the commercial proposals to plans and contracts prepared, marketed and controlled by the hospitals themselves.

The House of Delegates has never recorded its approval of or opposition to the prepayment method of providing hospital care, *per se*. The Judicial Council in 1931 reported as follows on plans involving a combination of hospital and medical services:

Within the last year some community hospitals have announced their intention to provide medical surgical and hospital service to families on a flat rate basis. In at least one instance such service has been offered to families for \$35 a year irrespective of the number of members in such families. In most instances certain exceptions are made, in that persons with chronic diseases are not entitled to receive the benefits of the plan and obstetric service is not supplied without additional compensation. The members of the Judicial Council doubt that it is wise to lead the people in any community to believe that all necessary medical and hospital service even though chronic diseases and obstetric care be excepted can be provided for the average family for \$35 a year. In the cases presented to it the Judicial Council has advised against the adoption of such plans by community hospitals because it is believed that they are not economically sound in that they may be unfavorably affected by conditions entirely beyond control under which contracts cannot be fulfilled. There are other aspects of the matter that readily present themselves for consideration involving the interests of physicians in the community who cannot participate in such plans.

The promoters of group hospitalization declare that the schemes they propose are merely service contracts. It was pointed out, in a study made by the Bureau of Medical Economics, published in the *AMERICAN MEDICAL ASSOCIATION BULLETIN* for October 1933, that group hospitalization contracts are insurance contracts. But the relationship of hospitals to state insurance departments and law observance, and the liability which a particular form of contract may impose on the contracting hospitals, are not the only items of importance in this newer method of marketing hospital services.

The nature of the contract is of vital concern to the medical profession. If hospitals are permitted to include medical services in their contracts for hospital care, the avenue is opened and the precedent is set for the practice of medicine by hospitals. Furthermore, it is possible that some hospitals that should be closed may, by the assistance of a group hospitalization scheme continue to serve the public badly.

At present there is a wide variation in the status of group hospitalization schemes. Some are being operated with the sanction and active assistance of county medical societies, others are being operated in communities in which the county medical societies maintain a position of noninterference but close observation, in some places the medical societies have succeeded in having hospitalization contracts drawn so as to exclude all medical services, while in other sections the group hospitalization contracts include varying amounts of medical services and thus make it possible at a later date to add more and more medical care under the guise of hospitalization. There is grave doubt that any group hospitalization schemes are using actually sound bases for premium rates.

The theory of the insurance principle in the provision of hospital care appears to be sound, but in the application of this principle to hospitalization, as in the field of sickness insurance, numerous opportunities for perversion and abuse are offered and many of the dangers inherent in sickness insurance practice are introduced. The most important of these dangerous tendencies have already been mentioned, *viz*, failure to limit the contract coverage solely to hospital care, and the possibility of keeping active some undesirable institutions that, for the public good, should be closed.

The Bureau has a record of fifty-five group hospitalization plans that are now operating or have been discontinued. There are forty-four more plans that have been proposed but as yet are not operating.

FEDERAL PROGRAM ON ECONOMIC SECURITY

As soon as it was learned that the President's Committee on Economic Security proposed to include medical services in the economic security program the facilities of the American Medical Association were offered to both the Secretary of Labor, Hon. Frances Perkins, chairman of the committee and Mr. Edwin E. Witte, executive director, for such assistance as might be given in the proposed studies. It was announced that medical interests would be recognized and safeguarded by the appointment of a medical advisory board composed of distin-

guished physicians and surgeons to consider the medical phases of the economic security program, but it was stated emphatically that no medical organization would be allowed representation on the board and no announcement of the names of the members of that board would be made public until just before the first called meeting of the board. Before the close of the first meeting of the Medical Advisory Board in Washington, Nov. 15, 1934, it was agreed that the Technical Staff should be enlarged to include Mr. Michael Davis, Mr. Nathan Sinai, Mr. A. M. Simons and Dr. R. G. Leland, as associate members.

The Medical Advisory Board was called for two meetings, Nov. 15, 1934, and Jan. 29, 1935. The Technical Staff met with the Medical Advisory Board on these dates and held two additional meetings Dec. 12, 1934, and Jan. 19, 1935.

Throughout the work of the Technical Staff on the President's Committee on Economic Security in preparing a Program for Social Insurance Against Illness, the associate staff members from the Bureau of Medical Economics of the American Medical Association offered comments pertaining especially to technical organization and administrative details of the proposed specifications for a federal sickness insurance act.

Since it was clearly pointed out by Secretary Perkins and Mr. Edgar Sydenstricker at the outset that the question of merit concerning a sickness insurance system for the United States was not open for discussion by the Technical Staff or the Medical Advisory Board, but that these groups were charged with the task of preparing the best possible proposal for the United States, in the event that sickness insurance was to become a reality, the participation of the associate members from the Bureau in the work of the Technical Staff might appear to be altogether in conflict with the established policy of the House of Delegates of the American Medical Association. However, in the work of the Technical Staff the associate members from the Bureau of Medical Economics consistently maintained the position that whether any points in the discussions were passed or agreed on, with or without reservations, the members of the Bureau, R. G. Leland and A. M. Simons, reserved the right to submit further observations, objections and reservations after study of the amended or final report. Moreover, it was repeatedly asserted that the participation in these discussions and studies by members of the Bureau of Medical Economics was in no way binding on any officer, department or body of the American Medical Association. It was agreed by all members of the Technical Staff that the American Medical Association should be entirely free to challenge the entire proposed sickness insurance program in any way that might seem proper, after the final report of the Committee on Economic Security had been acted on by the President and his decision had been announced.

COUNTY MEDICAL SOCIETY PLANS

In certain sections of the United States, county medical societies have been operating plans for the care of the indigent for more than thirty years.

The growing interest of social workers, philanthropists and foundations in the development of medical plans, services and institutions under lay control has caused an increasing apprehension and unrest in the medical profession. Adhering to the premise that medical services should be controlled by physicians, since by reason of training, licensure and experience they are the only persons competent to judge the necessity for and quality of medical care, medical societies throughout the United States have begun the development of professionally controlled medical services for people of low incomes, as well as the indigent.

Encouraged by the 'Ten Principles' adopted by the House of Delegates in Cleveland in 1934 and firm in the conviction that complete medical care for a community can be made available without state control, about one hundred county medical societies are now conducting or are about to initiate medical service experiments to demonstrate that American medicine need not follow the pattern of foreign sickness insurance schemes and practices.

Several of these county medical society plans appear to be gaining rapidly in favor with the public and in approval of the medical profession. Critical appraisal of these efforts should

however, be deferred until sufficient time has elapsed to provide for adjustments and perfection of the plans according to cumulative experience.

CONTRACT PRACTICE

Contract practice continues to hold an important place in medical economics problems. Although the Bureau of Medical Economics files will probably never show a complete census of all contract practice organizations or schemes, there are on record 748 such schemes, either proposed or in operation, some of which have been discontinued either voluntarily or because of court action. The California State Board of Medical Examiners has been particularly active in assisting the courts to catch up with contract practice fakery.

COLLECTION AGENCIES

Collection agencies and the collection type of finance companies and corporations continue to be of considerable annoyance to physicians. Notwithstanding the articles that have appeared frequently in *THE JOURNAL* and the *BULLETIN*, physicians continue to be duped by glib-tongued, high-powered collection agency salesmen who promise results impossible of attainment and often succeed in maneuvering the physician into signing a one-sided but within-the-law contract. In the files of the Bureau of Medical Economics there is a record of 1,132 collection agencies that handle medical accounts. The Bureau reprint "Collecting Medical Fees" deals with this subject.

HEALTH AND ACCIDENT, LIFE, CASUALTY AND MALPRACTICE INSURANCE

Many requests come to the Bureau for information concerning insurance companies writing life, health and accident, casualty or malpractice contracts. Data in these fields are secured from the most authentic sources and are forwarded to inquirers as confidential. Although it is impossible for the Bureau to make decisions for individuals as to the choice of an insurance company unless there should be but one company in a stated field, it is urged that persons buying insurance contracts take the time to study or investigate the contract provisions, satisfy themselves as to the financial standing of the company, and determine whether the company is licensed in the state in which the purchaser is a resident.

The Bureau has made some investigation of and had correspondence relating to 198 insurance companies of various types.

CARE OF THE INDIGENT SICK

In October 1933 a schedule was sent to state medical society secretaries to secure data pertaining to the medical care of the indigent. In April 1934 another schedule was sent to the secretaries of state medical societies asking for the details of organization and the manner of operation of the federal emergency relief plan for the care of the indigent.

Considerable research was conducted to find, if possible, the basis of the customs, methods and legal provisions on which the present system of medical care for the indigent rests.

A somewhat different approach to the status of federal emergency relief was made by Dr. W. C. Woodward, director of the Bureau of Legal Medicine and Legislation, who also sent a schedule to secretaries of state medical societies requesting information of a somewhat different nature than that requested by the Bureau of Medical Economics.

All available information was assembled in a report entitled 'Care of the Indigent Sick.' That portion of this report which deals with emergency relief measures and methods is accurate only as of December 1934 when the report went to press. Several changes in the state and local emergency relief organizations and methods have been reported since that time.

It was hoped that this report would serve to show the need for and indication of some methods by which the medical care for the indigent might be improved.

DISTRIBUTION OF PHYSICIANS

During the time that could be found in the midst of other work, a study was made of the distribution of physicians listed in the 1931 American Medical Directory. The 156,339 physicians listed have been arranged in fifty-four tables according to geographic distribution, size of community, type of practice and age. Graphic presentations of the statistical data are to be found in fifteen charts. The distribution according to length

of practice has not been completed but will appear later as a supplement to the main report

Several studies of the distribution of physicians have been made. The first of these studies was made by Myers and Harrison and was published in 1924 under the auspices of the General Education Board. Other studies of a similar nature have comprised only single states or cities. As far as is known, the analysis just completed by the Bureau of Medical Economics represents the most complete and detailed study to date.

COUNTY MEDICAL SOCIETY AND WORKMEN'S COMPENSATION FEE SCHEDULES

Since March 1931, when the Bureau was established, an effort has been made to collect fee schedules from county medical societies. Thus far the Bureau files contain fee schedules from 383 county medical societies in forty-four states and the District of Columbia and Panama. These schedules have been combined to form a composite list of all the items enumerated. This composite list contains 530 items. Such a schedule is entirely too detailed for practical purposes. For reference work the fees mentioned in the 383 schedules have been arranged to show the minimum and maximum in each state represented. For the entire number of schedules a weighted average was taken for comparison with individual county fees on any particular item.

Since fee schedules where deemed advisable must be based on local conditions, it is not the intention of the Bureau to suggest any nation-wide uniformity. County medical societies should establish their own lists based on a careful study of local factors.

It is not contemplated that the Bureau information on this subject will be published.

In its report entitled *Medical Relations Under Workmen's Compensation* published in March 1933 the Bureau of Medical Economics included some of the more commonly used workmen's compensation fee lists. The complete workmen's compensation fee schedules for eighteen states are on file in the Bureau, and with these as with the county medical society fee schedules, a weighted average has been taken for the eighteen states with which to compare separate state items.

Workmen's compensation fee schedules show some wide variations on certain of the more difficult medical and surgical procedures. When these items in the workmen's compensation schedules are compared with the county medical society schedules in the same state, there are again wide differences.

It is our opinion that the responsibility for securing modification of these schedules, if it is thought desirable, should rest with the medical profession in the several states.

UNIVERSITY AND COLLEGE STUDENT HEALTH SERVICE

The study of health services in colleges and universities has progressed as rapidly as possible. Because of the relatively greater importance of other work, it has been necessary to give this study a place of secondary importance.

A preliminary inquiry sent to 329 colleges and universities brought replies from 294 stating that these colleges had student medical services, and from nineteen, that these colleges did not maintain such services. Another schedule was then sent to those colleges having student medical services.

To date, 184 colleges and universities have returned the schedule filled in. The analysis and tabulation of replies and a report of the findings will be completed as soon as possible.

GENERAL ACTIVITIES

During 1934 the director appeared before six state medical societies, one state dental society, five county medical societies, and four other groups. During the year twenty-six addresses were delivered before nearly 5,000 physicians and twenty-eight conferences were attended at which 755 physicians were present.

PLANS FOR THE PRESENT YEAR

1. There seems to be no way in which to predict a stability of medical economics interests or the importance which different phases of medical economics may assume. At present it seems likely that much of the effort of the Bureau will be required for an indefinite period in the field of sickness insurance.

2. The study of health services in colleges and universities will be completed.

3. There is an increasing demand for information on medical services in industry. An attempt will be made to collect data on this subject.

4. An effort will be made to keep the Bureau files up to date on the subject of state and county medical society activities with special reference to medical economics.

MEDICAL PHASES OF RELIEF ADMINISTRATION

1. Has a definite agreement been concluded between the State Medical Association and the Relief Administration?
2. If not, what were the obstacles to forming an agreement?
3. If an agreement has been made, how long has any definite arrangement been in actual operation?
4. How many county societies are working under this agreement?
5. Have payments been made regularly to physicians for their services in accordance with this arrangement?
6. What arrangements, if any, have been made concerning clinics?
7. If clinics are used to supply medical care under the Relief Administration, what are the arrangements made with physicians serving in these clinics?
8. What is your opinion as to the effects on the medical profession and the public of the effort to supply medical services under Rules and Regulations No. 7 and succeeding arrangements in connection with federal relief? A rather full reply would be appreciated.

SCHEDULE ON MEDICAL ECONOMICS

To The Bureau of Medical Economics Chicago, Illinois
Date 1935
American Medical Association
State Medical Society with headquarters at
City, President, Secretary, State Address, Address

D. Care of the Indigent Sick

1. What is the legally provided method of furnishing medical care to the indigent in your state?
2. If your state has published a summary of the poor laws, where may it be obtained?
A. What is the governmental unit charged with the provision of medical care for the indigent? (Name of official or body)
(a) County
(b) Township
(c) City
3. What standards of indigency have been established?
4. What is the method of payment for medical care for the indigent?
A. Contract with individual—
(a) County physician
(b) Township physician
B. Are they paid for full time or part time services?
5. What are the duties of such employed physicians? (Full or part time)
(a) Care of institutional poor (Jail, poorhouse, children's homes or orphanages)
(b) Outpatient (home) care
(c) Health officers
6. How fully do employed county or city physicians meet the local demand?
7. What arrangements are made to pay for medical care in addition to that furnished by County, City or Township physicians?
8. Have any County Medical Societies in your state contracted with county or city officials to render medical care to indigents? (If so, please give list of such county medical societies.)
9. What actions have County Medical Societies taken with respect to medical care of the indigent aside from such contract?
(a) Established fee schedule
(b) Cooperation with authorities
(c) Any other actions
10. What changes have been made in methods of medical care for indigents during the past four years?
11. Is the present system satisfactory?
12. Was it satisfactory before 1929?
13. What are main defects?
14. Has the State Medical Association or any County Medical Society made any special study of the care of indigents?
A. If so, is the result of the study or studies available?
15. What, if any, arrangements have been made by the State Medical Association or County Medical Societies with emergency relief bodies? (For example, The Federal Emergency Relief Administration.)

Please send complete file of regulations, forms, used contracts, agreements, rules of procedure, etc. for the Bureau of Medical Economics files.

Bureau of Legal Medicine and Legislation

FEDERAL LEGISLATION IN GENERAL

When the last report of the Bureau of Legal Medicine and Legislation was written, the second session of the Seventy-Third Congress was in progress. No legislation of interest to physicians was enacted after that report was made.

The Seventy-Fourth Congress convened in its first session Jan. 3, 1935, and is still in session as this report is being written.

(March 29) Various bills of interest to the medical profession are pending, among them bills looking toward the establishment of "social security," with the possibility of the establishment of a federal state system of health insurance, food, drug and cosmetic bills, and a bill for the continuance of relief work under the Federal Emergency Relief Administration, with every prospect of an extensive program of public works in that connection, calling for an increase in the number of federal employees entitled to medical services under the United States Employees' Compensation Act. The more important of these bills are discussed later.

STATE LEGISLATION IN GENERAL

In 1934 the legislatures of nine states met in regular sessions and twenty eight special sessions were held in these and other states. During the current year the legislatures of forty-three states have already convened in regular sessions. In two of the states in which regular legislative sessions have been held special sessions also have been held and special sessions have been held in two other states. All bills of medical interest introduced in all these legislatures were studied and appropriate notices of their introduction with analyses of the bills when indicated, were sent to the presidents, secretaries and chairmen of the legislative committees of the interested state medical associations. Abstracts of these bills were published in *THE JOURNAL*, with the reports of their progress.

A survey of all legislation of interest to the medical profession considered by state legislatures during 1934 was published in the *AMERICAN MEDICAL ASSOCIATION BULLETIN* November 1934. On the whole, little legislation of interest to the profession was enacted. No legislation relating to healing cults was added to the statute books. A hospital lien law was enacted in Iowa. New Jersey's lien law was amended so as to authorize liens for physicians as well as for hospitals.

Most of the legislatures that convened in 1935 in their regular sessions are still in session as this report is being written (March 29). It would be productive of little good to discuss in detail the various measures now pending. A hospital lien law has been enacted in North Dakota and bills to authorize such liens are pending in other states. Basic science laws are pending in three states. Amendments to the medical practice acts of Arkansas and Oregon have been adopted. Vermont has amended both its chiropractic and its osteopathic practice acts. Arkansas and Colorado have forbidden the retail sale of barbitals and similar hypnotic drugs except on the prescription of licensed physicians, dentists and veterinarians. The outstanding feature of pending legislation is, however, the Uniform Narcotic Drug Act formulated by the National Conference of Commissioners on Uniform State Laws and approved by the American Bar Association and the American Medical Association. This act will be discussed later, together with some of the other more important pending state legislation.

Note. Since the foregoing section of the report was written there have been enacted a basic science act in Iowa and a naturopathic act in Arizona.

FEDERAL HEALTH INSURANCE

In a message to Congress June 8, 1934 the President announced as one of the main objectives of his program the establishment of "the security of the men, women and children of the nation against certain hazards and vicissitudes of life." To formulate that part of his program relating to this matter the President appointed a Committee on Economic Security. On Jan. 17, 1935 the President submitted to Congress the report of that committee and recommended legislation to establish unemployment compensation and old age benefits, to authorize federal grants to states to aid homeless neglected dependent and crippled children, and to provide additional federal aid to state and local public health agencies and to strengthen the United States Public Health Service. With respect to health insurance the President said:

I am not at this time recommending the adoption of so-called health insurance, although groups representing the medical profession are cooperating with the Federal Government in the further study of the subject and definite progress is being made.

The President's Committee on Economic Security, however, in its report to the President, which he transmitted to Congress, was outspoken on the subject of health insurance, saying:

The committee's staff has made an extensive review of insurance against the risks of illness including the experience which has accumulated in the United States and in other countries of the world. Based upon these studies the staff has prepared a tentative plan of insurance believed adequate for the needs of American citizens with small means and appropriate to existing conditions in the United States.

The committee stated in its report eleven objectives, which it described as the fundamental goals of health insurance, but it did not disclose the tentative plan prepared by its staff.

On the day on which the President's message was submitted to Congress a bill was introduced to make its recommendations effective, 'A Bill to alleviate the hazards of old age, unemployment, illness, and dependency, to establish a Social Insurance Board in the Department of Labor, to raise revenue, and for other purposes.' In the Senate this bill, S. 1130, was introduced by Senator Robert F. Wagner of New York and referred to the Committee on Finance. In the House of Representatives it was introduced by Representative Robert L. Doughton of North Carolina, H. R. 4120, and again by Representative David J. Lewis of Maryland, H. R. 4142 and both bills were referred to the Committee on Ways and Means. This bill is now commonly referred to as the Wagner-Doughton-Lewis bill.

Other bills have been introduced in the Senate and in the House of Representatives thirty-three in all, without administrative support, proposing the establishment of systems of so-called social insurance. Some propose specifically the establishment of federal systems of health insurance. Others propose systems of unemployment, old age and social insurance but are susceptible of being construed as authorizing the establishment of systems of health insurance also. These bills have been referred to various committees in the Senate and in the House.

The Senate Committee on Finance gave lengthy hearings on the Wagner-Doughton-Lewis bill. The Committee on Ways and Means of the House of Representatives followed a similar course. In the House of Representatives, the Committee on Labor held hearings on the bills referred to it. On March 15 while the Wagner-Doughton-Lewis bill was still pending before the Senate Committee on Finance and the House Committee on Ways and Means the House Committee on Labor reported to the House of Representatives one of the bills that had been referred to the committee with the recommendation that it pass, H. R. 2827 a bill for the establishment of unemployment, old age and social insurance, and for other purposes, introduced by Representative Ernest Lundeen of Minnesota. Promptly after the report of this bill its proponents sought to induce the House Committee on Rules to bring in a rule to facilitate its speedy consideration. At present writing (March 29) the bill sometimes known as the Lundeen bill is still on the House calendar, and the Committee on Rules has brought in no rule in its favor. The bill authorizes and directs the Secretary of Labor to provide for the immediate establishment of a system for unemployment insurance and of "other forms of social insurance for the purpose of providing compensation for all workers and farmers who are unable to work because of sickness, old age, maternity, industrial injury, or any other disability."

The title of the Wagner-Doughton-Lewis bill specifically denominates it as "A Bill to alleviate the hazards of old age, unemployment, illness, and dependency, to establish a Social Insurance Board in the Department of Labor, to raise revenue, and for other purposes." Only once however does the text of the bill refer specifically to health insurance. The bill proposes to establish in the Department of Labor a Social Insurance Board which, among its various duties, shall have the duty of—

Studying and making recommendations as to the most effective methods of providing economic security through social insurance and as to legislation and matters of administrative policy concerning old age insurance, unemployment compensation, accident compensation, health insurance and related subjects.

Obviously when the title of the Wagner-Doughton-Lewis bill describes it as "a bill to alleviate the hazards of old age, unemployment, illness, and when the bill itself proposes to charge the Social Insurance Board with the specific duty of studying and making

recommendations as to legislation and matters of administrative policy concerning health insurance and related subjects," it is to be assumed that the bill looks toward the establishment of a federal health insurance system, a system either independent of state systems or correlated with such systems. It has been suggested that the situation be clarified by eliminating the specific reference to "health insurance" as one of the fields of activity assigned to the proposed Social Insurance Board. The elimination of those words, however, would be hardly more than a gesture, for the board would still be charged with the duty of studying and making recommendations to determine 'the most effective methods of providing economic security through social insurance' a duty certainly broad enough to cover health insurance.

The Wagner-Doughton Lewis bill proposes to extend the federal subsidy system of the Sheppard-Towner maternity and infancy act to a field much larger than has ever heretofore been contemplated. It ignores the fact that federal subsidies by inducing states to appropriate money for federal state projects that but for such subsidies would not have been appropriated have already contributed toward bringing many states to the brink of bankruptcy, if such subsidies have not already led them into the abyss. It is true that the bill authorizes the almoners of the federal government for the relief of such distressed states, to pay the state's contribution necessary to enable it to obtain federal subsidies for projects that are to be undertaken in the name of social security but the subsidy system thus tends further to promote improvidence in some states and, by reason of the increased contributions that citizens of better organized and more thrifty states will have to pay, tends only to bring even those states into bankruptcy. As is always the case, moreover, the subsidy system is coupled with federal supervision and control over the states in the exercise of rights that under the constitution they are entitled to exercise independently.

In providing for such federal supervision and control of the activities of the several states, the Wagner-Doughton-Lewis bill proposes to perpetuate the mistake made in the Sheppard-Towner maternity and infancy act and to entrust to the Children's Bureau in the Department of Labor medical and public health functions that should rightly be exercised, if they are to be exercised at all by the federal government, by the United States Public Health Service. Without reflecting in any way on the services rendered by the Children's Bureau in its own statutory field, the proposal to create within that bureau a medical division—and this will be necessary if the bureau is to exercise medical functions—has nothing to commend it.

Note On April 4 Representative Doughton North Carolina, introduced a redraft of the Wagner-Doughton-Lewis bill. The redraft was reported favorably by the House Committee on Ways and Means April 5 and passed the House April 19. The redraft omits from its title all reference to illness. The name of the proposed Social Insurance Board is changed to "Social Security Board, and no duty is devolved on the board to study and make recommendations with respect to health insurance. Corporations organized and operated exclusively for religious, scientific, literary or educational purposes no part of the net earnings of which inures to the benefit of any private shareholder or individual are not liable to the assessments provided in the redraft for old age or unemployment benefits, nor apparently, are employees of such corporations to be entitled to such benefits. The redraft provides, as did the original bill, federal subsidies, contingent on state plans being acceptable to federal agencies, to promote maternal and infant welfare, to care for crippled or dependent children, to provide for child welfare services, and for the development of state and local health work.

STATE HEALTH INSURANCE

The President's Committee on Economic Security, in its report to the President, transmitted by him to Congress, said

The rôle of the Federal Government is conceived to be principally (a) to establish minimum standards for health insurance practice and (b) to provide subsidies grants or other financial aids or incentives to States which undertake the development of health insurance systems which meet the Federal standards.

In anticipation of the enactment of federal health insurance legislation along the lines laid down by the committee, the draft of a model bill, intended to promote the establishment of state health insurance systems, was prepared under the auspices of the American Association for Social Security, Inc. This bill is commonly referred to as the Epstein bill, taking its name from one Abraham Epstein, the executive secretary of the association under the auspices of which the bill was developed. Analyses of this bill have been so widely distributed that it seems unnecessary to repeat them here. It is sufficient to say that the bill proposes the establishment in each state of a system of health insurance covering practically every form of medical, nursing and hospital service, to be administered by an all powerful state board, made up predominantly of laymen. Probably the most significant feature of this bill and of the propaganda in its favor is the absence of actuarial estimates of its probable cost. The fact that tax rates and premiums are fixed in the bill indicates that estimates of costs have been made, but for reasons that the proponents of the measure deem sufficient the public, which must in the end pay the cost of any such measure, is kept in the dark. The Epstein bill has been introduced in the legislatures of Massachusetts Nebraska and New York. A somewhat different health insurance bill has been introduced in the legislature of Pennsylvania. In California, seven bills purporting to be health insurance bills have been introduced by title only, apparently leaving the committees to which these titles have been referred the task of drafting bills under them. In no state has a health insurance bill been enacted.

FEDERAL EMERGENCY RELIEF ADMINISTRATION

The Federal Emergency Relief Administration continues to provide medical relief, following in a general way the provisions of Rules and Regulations No 7. These rules and regulations are clearly mandatory in their terms and only by having them mandatory can federal funds for medical relief be properly apportioned. A considerable leeway seems to have been conceded however, to state emergency relief administrators in the interpretation of these rules and regulations with resultant variations in standards for medical relief and in payment for medical services in the several states. The situation has been improved, however by the assignment of Dr Clifford E. Waller, Assistant Surgeon General United States Public Health Service, to duty as medical director of the Federal Emergency Relief Administration. It is hoped and expected that under his direction an efficient, economical system of medical relief will be worked out in every state, satisfactory alike to the administration, to the public, which must pay the bills and to the medical profession.

Unfortunately the problem of medical relief is likely to be complicated by the practically assured adoption of H J Res 117, a joint resolution making appropriations for relief purposes. This is the resolution that proposes to place at the President's disposal, for relief purposes, approximately \$5,000,000,000. So far as direct medical relief is concerned there is no reason why the adoption of this resolution should affect any change from present practices. The resolution, however, contemplates an extensive program of public works, and to the extent that such construction is undertaken directly by the federal government, through its own employees, there will be a large increase in the number of persons entitled to medical services under the provisions of the United States Employees Compensation Act of 1916, as amended (United States Code Title 5, Sec. 785), and as modified by the provisions of An Act Making an additional appropriation to carry out the purposes of the Federal Emergency Relief Act of 1933, for continuation of the Civil Works program, and for other purposes approved Feb 15, 1934 (48 Stats 351). To these federal employees, as will be recalled, medical and hospital service will have to be given by United States medical officers and in United States hospitals wherever they are available, and where no such officer or hospital is available by physicians and hospitals designated or approved by the United States Employees Compensation Commission. The provision of the statute that limits the choice of an injured employee of the United States government to United States medical officers and hospitals or to physicians and hospitals designated by the commission is inconsistent with the principle

uniformly contended for by the American Medical Association. In view, however, of the large claims for compensation, present and future, that will grow out of injuries to government employees sustained in the discharge of their duty and in view of the difficulty that inexperienced and inadequately instructed physicians must have in filling out the elaborate reports called for in connection with government services, regarded apparently as necessary to facilitate the fair adjustment of claims there are grave difficulties in pursuing any other course.

It is assumed, of course, that such medical and hospital services as are rendered to government employees under the projected public works program will be restricted to the relief and cure of injuries sustained by employees who incur illness or injury in the line of duty and that medical and hospital services to such employees for illness or injury incurred otherwise and services to their dependents, will be paid for by the Federal Emergency Relief Administration where the government salary is inadequate to enable the employee to provide the necessities of life for himself and his dependents or by the employee himself whose salary is adequate, with incidental free choice of physicians and hospital.

Note H J Res 117 became a law April 8. So far as the problem of medical relief is concerned, the form in which the resolution was enacted necessitates no revision of the foregoing remarks.

FEDERAL FOOD, DRUG AND COSMETIC LEGISLATION

Three bills of major importance are pending in the Seventy-Fourth Congress for the better regulation of foods, drugs and cosmetics, namely, S 5, introduced by Senator Copeland of New York, S 580, introduced by Senator McCarran of Nevada and H R. 3972, introduced by Representative Mead of New York and then reintroduced by him in a modified form as H R. 6906.

The Senate Committee on Commerce gave an extended hearing on the bill introduced by Senator Copeland. The American Medical Association was represented at the hearing and subsequently filed a brief, on both occasions suggesting changes designed to strengthen the bill. The committee reported the bill March 23, with minor modifications and with the recommendation that it pass. The bill as reported is in effect a revision and extension of the Federal Food and Drugs Act of 1906. It proposes to extend federal control to remedial agents so as to make it cover interstate and foreign commerce devices and appliances of all kinds intended for therapeutic purposes and to cover cosmetics. Broad provisions are made for regulating the advertising of foods, drugs and cosmetics. Authority is granted to the Secretary of Agriculture to license food producing establishments, to promulgate regulations and to fix limits of tolerance and in certain cases, standard tests. Advisory boards are to be set up to aid the secretary in the formulating of regulations and possibly in certain other activities.

It is to be hoped that if this bill is to be enacted it will be materially strengthened and improved in form. To class all manner of therapeutic devices as 'drugs' and to prescribe for them the same standards of adulteration and misbranding as are prescribed for the "drugs" of ordinary parlance is illogical and hardly calculated to facilitate the enforcement of the act. The language inserted to satisfy the demands of cultists fearing lest the act might interfere with some of their practices is confusing. The definition of 'medical opinion' is impossible. The requirement that physicians' prescriptions in the District of Columbia, and elsewhere if they enter into interstate commerce bear statements on the labels showing the active ingredients contained in them is unreasonable and uncalled for. The required declarations on the labels, to show the ingredients in certain types of foods and drugs, will convey but little useful information to purchasers, because the bill as reported does not require the quantity of each active ingredient to be stated or require even that the names of the ingredients be stated in the order of their relative quantities in the mixture. Action looking toward strengthening this bill has already been taken.

Note On April 1 the Copeland bill was made the unfinished business of the Senate. For the ensuing week the bill was discussed on the floor of the Senate and numerous amendments were adopted. On April 8 however the Senate dis-

placed the Copeland bill as the unfinished business by voting to take up another bill for consideration. The Copeland bill was thus returned to the Senate calendar and thereby lost its privileged status.

FEDERAL AND STATE NARCOTIC LEGISLATION

Two bills are pending in Congress to regulate the distribution of cannabis in interstate and foreign commerce, S 1615, introduced by Senator Hatch of New Mexico, and H R 6145, introduced by Representative Dempsey of the same state. Other than this, no federal narcotic legislation is pending. In the states, rapid progress is being made toward the enactment of the Uniform Narcotic Drug Act formulated by the National Conference of Commissioners on Uniform State Laws and approved by the American Bar Association and the American Medical Association. Narcotic laws literally or substantially in this form have been enacted as follows: In 1933 by Florida, New Jersey, New York and Nevada. In 1934 by Louisiana, Kentucky, Rhode Island, South Carolina and Virginia. In 1935 up to the present date (March 29) by Arizona, Colorado, Georgia, Indiana, Nebraska, New Mexico, South Dakota and Utah. Legislation similar in many respects, but not identical, was enacted in 1935 by Oregon and West Virginia. Bills identical with the Uniform Narcotic Drug Act are now pending in Connecticut, Delaware, Illinois, Maine, Massachusetts, Minnesota, Missouri, Ohio and Wisconsin.

Note Since the foregoing section of the report was written, a uniform narcotic drug act has been enacted in Delaware.

State medical examining and licensing agencies have been criticized in some cases because they do not promptly suspend or revoke the licenses of physicians reported to them by the United States Bureau of Narcotics as being narcotic addicts, in the judgment of the officers of that bureau, and the licenses of physicians whom the bureau alleges have been convicted of violating federal or state narcotic acts. When the evidence submitted by the officers of the bureau warrants such action, the licenses of such physicians should be suspended or revoked according as the circumstances of the case indicate, if in the judgment of the state agency, suspension or revocation is the procedure best calculated to serve the interests of the public and of the medical profession. Where authority for such suspension or revocation does not exist, it is desirable that an effort be made to procure legislation conferring that authority, in order that the medical profession may be freed of the reproach of numbering among its members narcotic addicts and physicians who abuse the authority granted them to administer, dispense and prescribe narcotic drugs.

LICENSING OF FOREIGN PRACTITIONERS

Complaints from various sources have been received during the year of the influx of foreign physicians into the United States. Inquiry at the Bureau of Immigration showed that alien physicians had been admitted as follows: In 1929 398, in 1930, 390, in 1931, 329, in 1932, 259 in 1933 187, and in 1934 353, a total of 1,916. While the record showed no substantial diminution in the immigrant physicians entering the country, the total number of immigrants diminished from 279,678 in 1929 to 29,470 in 1934. The reason for the continued influx of foreign physicians is obvious when it is noted that the number coming from Germany increased from 22 in 1929, to 160 in 1934. There was no corresponding increase in immigrant physicians from any other country. The number coming in from Canada in the years named fell from 228 to 108. Of the 1,916 physicians who entered the country during the six years named, 755 announced their destination as New York.

These physicians have not been able to enter the United States, as many physicians seem to have supposed, because of an exemption of physicians from the requirements of the act that limits the number of immigrants who may come in each year from each of the several foreign countries, for physicians are not so exempted. They have been enabled to come in, apparently, because of the general diminution in the number of immigrants arriving from foreign countries, which has left the quotas of those countries unfilled and open to physicians or any other persons desiring to avail themselves of the privilege of coming to the United States. Whether such physicians may or may not practice medicine in the United States on their

arrival depends primarily on their ability to meet the requirements of the laws of the several states with respect to the practice of medicine. If they can do so, there seems at present no practicable way of limiting their immigration.

FEDERAL INCOME TAXES

The Revenue Act of 1934 made no change with respect to income taxes that are of special interest to physicians. During the year, however, a controversy arose between physicians practicing in Oregon and in the state of Washington and the federal officers charged with the collection of income taxes in those states and with the auditing of income tax returns concerning the deductibility, as a professional expense, of the cost of maintaining automobiles for professional service. Local officers of the Bureau of Internal Revenue, in auditing the returns of physicians for 1932, called on physicians for written records to show the mileage traveled by them in their automobiles in connection with their professional practices, to prove just what part of the expense of maintaining an automobile in each case was a personal expense and not deductible and what part was a professional expense and therefore deductible. During the year covered by the audit there had been no law or regulation in force requiring the keeping of such detailed mileage records, and many physicians were unable to comply with the unusual and unexpected demand. The matter was submitted through the Bureau of Legal Medicine and Legislation to the Commissioner of Internal Revenue, but without obtaining relief. Relief can be obtained, it appears only through appeals by taxpayers to the Commissioner of Internal Revenue, in Washington, to the Board of Tax Appeals and to the courts.

VETERANS' LEGISLATION

Several bills are pending proposing to reenact all laws granting benefits to veterans that were repealed by the act of March 20, 1933. Another bill would authorize the admission to any Veterans Administration hospital of any veteran, not dishonorably discharged on the payment of a per diem fee in an amount equal to the average cost of hospitalization per patient day at the hospital for the previous month. Other bills propose to establish additional hospitals, to provide medical and hospital services to persons not entitled thereto under the existing law and regulations relating to veterans, and to provide an increase in pensions for veterans. There is pending no legislation proposing to provide benefits for contract surgeons of the Spanish-American War comparable to the benefits provided for other persons of grades similar to that of the contract surgeon.

Note. From March 29 to date (April 23) approximately 20 bills have been introduced proposing to erect either new veterans general hospitals or additions to existing veterans' general hospitals, in the various states. The House Committee on World War Veterans' Legislation has arranged for an early hearing on the bills. Another bill has been introduced proposing generally to revise all veterans laws. This bill provides, among other things that the term "veteran" shall include any individual who served overseas as a contract surgeon in the army.

VIVISECTION LEGISLATION

Bills were introduced in New York and in Wisconsin proposing to prohibit experiments on living dogs for any purpose other than the healing or curing of the dog. The New York bill was defeated. The Wisconsin bill, and a bill in Congress prohibiting experiments on dogs in the District of Columbia, are pending at the time this report is made (March 29).

THE OPTICAL RETAIL TRADE CODE

Demands were made in the early part of the current year by the Optical Retail Trade Code Authority, on ophthalmologists practicing in various parts of the country, for the payment of assessments for the support of the code authority and for reports concerning the extent of business done. Inquiry of the National Industrial Recovery Administration at Washington disclosed the fact that those demands had been sent out to ophthalmologists who were supposed to be engaged in the commercial purchase and sale of eyeglasses and spectacles. Ophthalmologists were advised through letters sent to the secretaries of all state medical associations and through the pages of *THE JOURNAL* to disregard demands for the payment of assessments and for

the making of reports unless they were actually engaged in the purchase and sale of ophthalmic lenses and making a profit out of that commercial business as a matter distinct from their professional work.

Bureau of Health and Public Instruction

Much of the work of the Bureau cannot be presented in statistical form. Correspondence has increased from 6,593 pieces in 1932 to 9,148 in 1934, radio talks have increased from 171 in 1932 to 208 in 1934 and are now national in coverage instead of local, radio talks distributed for use of county societies have increased from 4,312 in 1932 to 7,495 in 1934.

As in previous years, the work of the Bureau has been concerned with "Questions and Answers," editorial duties in connection with *HYGEIA*, radio broadcasting over two national networks and over local stations, the maintenance of a radio library for state and county medical societies, cooperation with state and county medical societies in health education, preparation and distribution of material relating to protection of medical research representing the American Medical Association on advisory boards and committees of national lay organizations, writing of articles for publication, and the giving of talks to assembled audiences.

RADIO PROGRAM

The American Medical Association began in November 1933 a broadcasting program over a Blue network of the National Broadcasting Company, which was continued through June 1934 and resumed Oct. 1, 1934. This program made talks available roughly to forty stations, of which we are informed, about 75 per cent took the program on any given date, though only about twenty stations took all the programs. Correspondence however, shows that the more important stations, such as WJZ in New York and WENR in Chicago, did take the program regularly and therefore coverage was very good. In February 1934 arrangements were made with the Columbia Broadcasting System for a network program covering the southern and western part of the United States and giving virtually a complete coverage through approximately thirty stations from Chicago west, north and south to the Pacific coast. The total number of network talks thus broadcast was thirty-four on the National Broadcasting Company chain and forty-seven on the Columbia Broadcasting System. The facilities of both of the two great broadcasting systems have been made available without cost, and the Board of Trustees gratefully acknowledges their generous services.

A radio program consisting of twelve talks was delivered during the meeting of the American Medical Association at Cleveland. Through the courtesy of the National Broadcasting Company and Station WTAM, two network broadcasts and two local broadcasts were arranged. One of these network broadcasts took the place of the regular NBC program from Chicago. Through the courtesy of the Columbia Broadcasting System and Station WHK an exactly similar program was arranged. In addition, four local talks were given over Station WGAR.

The director of the Bureau has participated in broadcasting programs under the auspices of state associations and county societies in various places.

The radio library was increased during 1934 from 440 talks to 652 there being added in 1934 107 fifteen minute talks, eighty-three ten minute talks and twenty-two five minute talks. The total number of radio talks distributed has been stated already. The radio talks distributed to local and state societies included ninety-four county societies and sixteen state societies.

SERVICE TO STATE AND COUNTY SOCIETIES

In the discharge of its function as a clearing house of information on public health and health education for state and county medical societies, the Bureau conducted a survey in 1934 to establish an up-to-date record of activities in health education throughout the United States, such as radio programs, speakers bureaus, participation in community public health activities, use of press releases, participation in community health councils and other organized activities in relation to public health and health education. The details revealed by this survey have been embodied in a paper, which was read

before eight county medical societies and has been distributed in mimeographed form. There is no space here to do more than say that this survey discloses great activity in public health and health education on the part of state and county medical societies and an encouraging acceptance on the part of their communities of the interest expressed in public health and health education by the organized medical profession.

The clipping loan service of *HYGEIA* clippings has been continued, seventy-four such loans being made in 1934. Since old issues of *HYGEIA* grow scarcer as time goes by this clipping loan service will assume increasing importance. The correspondence exchanging suggestions and information between local society officers and the Bureau grows heavier month by month.

PROTECTION OF RESEARCH

The question of medical research involving animal experimentation is constantly being agitated by the antivivisectionists, particularly in centers where medical education is important. The animal experimentation fight seemed to be centered in Chicago in 1934 but there was also evidence of activity in New York, in Boston and in California. The Bureau has added new publications on this topic to its list of pamphlets. Arrangements were made also for educational talks on animal experimentation and the debt of science to animals over the regular network facilities described in the section of this report dealing with radio. Information has been furnished to local societies, and the Bureau made its annual presentation to graduating students in class A medical schools of one copy each of the pamphlets *The Dog's Gift to the Relief of Suffering* and *The Ethics of Animal Experimentation from the Viewpoint of a Philosopher*.

COOPERATION WITH LAY ORGANIZATIONS

By order of the Board of Trustees, the director is now acting as a member of the medical advisory board for the National Congress of Parents and Teachers (Summer Round-Up of the Children), the General Federation of Women's Clubs (Health and Welfare Department), the National Committee for Boys' and Girls' Club Work (4-H Club Movement) and the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association.

The printed matter to be officially distributed by the National Congress of Parents and Teachers in 1935 definitely states that preschool examinations whenever possible should be conducted by the family physician in his own office. Copies of this material have been distributed to all secretaries of state medical societies and to the secretaries of the fifty largest county medical societies, and in response the Bureau has received many expressions of approval and the encouragement to proceed with definite development of the policy thus initiated. A leaflet authorized by the National Congress of Parents and Teachers at the advisory board meeting in 1934 will inform physicians, dentists and nurses as to the objectives of the Summer Round-Up and will suggest methods for procuring examinations especially emphasizing the importance of referring all patients wherever possible to the family physician and dentist for examination. The committee to prepare this leaflet includes the director of the Bureau, a representative of the American Dental Association and a representative of the National Organization for Public Health Nursing.

There has been no further development in the cooperative relationships with the General Federation of Women's Clubs. The cancer education campaign previously outlined (1933 annual report of the Bureau of Health and Public Instruction) is going forward and seems to be proceeding satisfactorily and with due regard to the avoidance of hysteria. The federation continues to preserve an attitude of neutrality as regards controversial questions in the field of medical economics contenting itself with informing local clubs of sources of information including the American Medical Association.

The Joint Committee on Health Problems in Education met in February and by common consent the meeting was one of the best in recent years. The meeting was attended on behalf of the American Medical Association by four of its six repre-

sentatives, namely, Drs. Isaac A. Abt, Thurman B. Rice, R. G. Leland and the director of the Bureau. Absent members were Drs. A. J. Chesley of Minneapolis and Edward Jackson of Denver, both unavoidably detained. Their advice on matters pending before the committee was procured by correspondence. The committee discussed progress on a number of reports that were not ready for publication at the time of the February meeting. At least two of these reports, dealing respectively with conservation of sight of the school child and a study of school health service policies, progressed practically to the point of publication by the end of 1934 and will undoubtedly appear during the present year.

PERSONAL APPEARANCES

The director of the Bureau made sixty-eight addresses during the year to sixty-six different groups, audiences totaling 1,008 physicians in medical society groups, 15,662 persons in lay groups, and 310 in groups including both doctors and lay persons, total audiences, 16,980 persons.

EXHIBITS

In cooperation with the Bureau of Exhibit, the Bureau of Health and Public Instruction assisted in the planning of changes in the American Medical Association exhibit at A Century of Progress. An exhibit entitled "The Medical Profession and the Public Health" was shown at the American Medical Association annual session at Cleveland. The Bureau of Health and Public Instruction continues to cooperate closely with the Bureau of Exhibit in making exhibit material available with the consent of local medical societies, to public health or lay groups requesting such material.

PAMPHLETS AND REPRINTS

In view of the extensive revision of pamphlets undertaken by the Bureau in 1933 the necessity for such revision was less in 1934. Nevertheless the Bureau added eighteen titles to the lay catalogue, revised four titles and dropped nine titles. Reprints totaling 79,000 were sold.

QUESTIONS AND ANSWERS

The question and answer correspondence in 1934 showed an increase of about 15 per cent over 1933.

The number of Questions and Answers published in *HYGEIA* was seventy-eight, representing just under 1 per cent of the total questions. As the correspondence increases, naturally the proportion published which formerly ran as high as 6 per cent will steadily decrease.

For the second year of A Century of Progress the Bureau again prepared a selected set of 145 questions and answers, which were displayed as in the previous year. The Bureau of Exhibit has duplicated these sets and they have been effectively used in connection with local medical society exhibits and personal appearances for public addresses. This particular exhibit technique has also been used by other departments of the Association.

Bureau of Investigation

As has been emphasized in each annual report, the best index to the activities of the Bureau of Investigation is the amount of correspondence it handles during the year. In this connection it is interesting to go back over two decades and compare the number of inquiries that the Bureau received and answered in the decade from 1915 to 1924 inclusive as compared with the last decade from 1925 to 1934 inclusive. In the first of these ten-year periods the total number of inquiries received and answered was 37,388. In the second ten-year period the number of inquiries received and answered was 100,919 or an increase in the second period over the first of nearly 270 per cent.

These figures become more remarkable when it is borne in mind that during the second period—that is, between 1925 and 1934—a large amount of correspondence that had previously been handled by the Bureau of Investigation was turned over to other departments including the Council on Medical Education and Hospitals, the Bureau of Medical Economics, the

Bureau of Exhibits and the Committee on Foods. In spite of this the correspondence of the Bureau of Investigation has been maintained at around 11,000 letters annually. It is this work of answering inquiries from physicians and laymen that comprises the most important function of the Bureau, and it cannot too often be emphasized that such correspondence does not have the casualness of ordinary business. Dealing as it does with products, concerns and individuals of questionable standing, it carries with it a serious responsibility. In the twenty-eight years during which what is now called the Bureau of Investigation has been in existence, meticulous care has been exercised to see that no statements are sent out by the Bureau that are not justified by the facts and supported by documentary evidence.

The interest that was evinced in 1933 both by physicians and by intelligent laymen in the proposed new national legislation to extend the powers of the federal government over the sale, and particularly over the advertising, of nostrums extended through 1934. The continued low advertising standards maintained by many broadcasting stations with the resulting amount of fraudulent medical advertising that has gone out over the air has been responsible for the Bureau's receiving and answering thousands of inquiries about radio advertised nostrums and quacks.

The Better Business Bureaus of the country, the Federal Trade Commission, the Food and Drugs Administration, the Federal Communications Commission all continue to cooperate actively with the Bureau of Investigation.

During the past year the Bureau of Investigation has sought and received help from the Division of Investigation of the United States Department of Justice in getting information regarding the criminal records of certain impostors who have been swindling physicians.

The Bureau has continued to be of every possible help to governmental agencies when called on.

The number of inquiries received from teachers and students in educational institutions gets larger every year. It is no unusual thing for the Bureau within the period of a few days to receive scores of requests from members of a class that is making a study of "patent medicines" or quackery, whether from a health, economic or sociological point of view.

The director of the Bureau addressed thirty-seven audiences during the year in various cities in five states and the District of Columbia.

The demand for the pamphlets prepared and issued by the Bureau of Investigation continues. There has been an unusual demand for the Bureau's pamphlet "Cosmetics and Allied Preparations."

Material for a third volume of "Nostrums and Quackery" is being compiled. The plan is to make volume III much more condensed than either of the previous two volumes. While this will necessitate rewriting almost all the accumulated material, it is believed that the greater usefulness of the proposed book will repay the amount of extra effort involved.

Bureau of Exhibits

THE ANNUAL SCIENTIFIC EXHIBIT

The Scientific Exhibit at the Cleveland session was the largest in the history of the Association. For the first time all fifteen sections of the Scientific Assembly participated through special section exhibit committees. Sixty-three papers read before the sections were illustrated with exhibits on the same subjects a larger number than ever before.

The commodious hall at Cleveland facilitated the housing of 167 exhibits, compared to 120 the year before. The special exhibits, put on by special committees appointed for the purpose, included encephalitis, demonstrations in pathology, and nutrition. Ten of the section exhibit committees took part in special features, adding much to the success of the Scientific Exhibit as a whole. Among these features were two special exhibits on 'Home Delivery Technic' and 'First Aid in Eye Injuries', exhibit symposiums included amebiasis, thyroid diseases, treatment of burns, and cutaneous allergy, motion picture programs conducted on regular schedules were shown simultaneously in several parts of the hall.

THE CENTRAL SCIENTIFIC EXHIBIT

The Central Scientific Exhibit was dismantled in the headquarters building in December and the equipment and much of the material was lent to the Museum of Science and Industry, where a department for medical exhibits has been established. The exhibit material not lent to the museum was returned to the original donors.

ASSOCIATION EXHIBITS

Association exhibits divide themselves into two groups: those of a scientific nature dealing with the work of the Association or with medical science, and those of a more popular nature, for the public.

Exhibits for meetings of state and county medical societies and other scientific groups have been sent out twenty-six times during the year. The closest contact has been maintained with the various councils and bureaus of the Association in order that the work of the Association may be properly presented. In addition to exhibits portraying the work of the Association, there have been added from time to time, mainly from the annual Scientific Exhibit, exhibits dealing with various phases of scientific medicine, constituting in fact an effort at graduate medical education. The advice of the Council on Medical Education and Hospitals has been most helpful in regard to these. There has been prepared for distribution a list of twenty-one exhibits suitable for state and county medical meetings. The exhibits for public expositions, fairs and the like supplement the work of the Bureau of Health and Public Instruction, with which bureau there has been the closest cooperation. During the year exhibit material was sent to fifty different expositions and fairs, in most instances in the care of a state or county medical society in that area.

EXHIBIT AT A CENTURY OF PROGRESS EXPOSITION

During the five months of A Century of Progress Exposition in 1934, the exhibit of the American Medical Association was even more successful than in 1933. While the total attendance at the exposition was somewhat less in 1934, the crowds were more discriminating, resulting in a relatively larger proportion of visitors to the medical exhibits in 1934 than in 1933. Some changes and new material in the exhibits of the Association were made, but otherwise the exhibit was conducted on the same general plan as in 1933. In the visitors' book, kept only in 1934, 1,080 physicians registered from all parts of the United States, Canada, Europe and Asia. Several millions of persons visited the exhibit during the two seasons.

The exhibit material shown at A Century of Progress Exposition has been lent to the Museum of Science and Industry for inclusion in the medical exhibit at that institution.

MOTION PICTURES

During the year there were many hundred requests for motion pictures. The Association has no films suitable for lay audiences. The Bureau of Health and Public Instruction has prepared a list of film sources, however, which has been given wide distribution.

Films for medical audiences have been sent out on numerous occasions. The Council on Physical Therapy has collected several 16 mm films which have been very popular. The Association has, in addition to these, two 35 mm films for which there has been little demand recently because of lack of facilities in most communities to run them.

Committee on Foods

The membership of the Committee on Foods during 1934 was changed by the resignation of James S. McLester, M.D., professor of medicine, University of Alabama, consequent to his election as President-Elect of the American Medical Association, termination of the term of membership of Julius H. Hess, M.D., professor of pediatrics, University of Illinois School of Medicine, and the appointments of Joseph Brenne-mann, M.D., chief of staff of the Children's Memorial Hospital, Chicago, and Lydia J. Roberts, Ph.D., chairman and professor, Department of Home Economics, the University of Chicago.

The following is a statistical summary of products submitted, accepted and rejected, and acceptances withdrawn

Products submitted—Total up to Dec 31 1934	2 985
1932	632
1933	583
1934	1 125
Products accepted—Total up to Dec 31, 1934	2 317
1932	493
1933	490
1934	1 111
Products rejected—Total up to Dec 31 1934	91
1932	16
1933	41
1934	30
Withdrawals of acceptance—Total up to Dec 31 1934	64
1934	33

The volume of work of the Committee increased greatly over that of previous years. The number of foods submitted increased from 600 per annum for the two preceding years to more than 1,100. The number of inquiries regarding the Committee, of requests for information on foods and nutritional subjects, and food advertising and manufacture, from physicians, government officials, hospitals, educational institutions and the public, and the regular routine work have all been much greater than previously. The newly instituted control over accepted products that was put into effect added greatly to the duties of the office of the Committee.

RULES AND REGULATIONS

The Rules and Regulations were revised by the addition of a rule governing package label and advertising for special purpose foods' with usefulness restricted to specific purposes. This new rule specifies the information which in the interest of the public, should be given on the label and in the advertising for this type of products. Two new editions of the Rules were published.

GENERAL COMMITTEE DECISIONS

Eleven new General Committee Decisions were adopted and published in THE JOURNAL.

Adonics Claims in Lay Advertising
Advertising Dealing with Treatment of Disease or the Nutrition of the Sick, or Recommending any Special Type of Diet
Blood Building Claims in Advertising
Educational Food Advertising
Energy Claims for Foods
Iron Claims for Foods
Pasteurization of Milk
Resistance Claims in Food Advertising
Special Purpose Foods for Diets Restricted in Dextrose Formers
Sweets in the Diet Especially of Children
Vitamin E Claims for Public Advertising

These decisions explicitly define the Committee's judgment on the particular topics and serve as guides for passing on advertising for accepted products. The General Decisions of the Committee now total fifty-one.

There is a constant demand for copies of the booklet of Committee decisions from advertising agencies, members of the food industry and others. Apparently they are being found to be useful and practical. A number of the decisions are especially helpful in preparing replies to inquiries from physicians and members of other professions for authoritative opinions on important current food or nutritional issues. In certain instances, manufacturers have indicated that the decisions are helpful in planning new food or advertising projects.

RECOMMENDATIONS FOR AMENDMENT OF FEDERAL FOOD AND DRUGS ACT

The experience of the Committee gained in the last five years in passing on foods and food advertising has particularly emphasized the need for radical amendment of the present Food and Drugs Act that it may more effectively protect the health, good nutrition and economic interests of the public. Accordingly, twenty distinct recommendations were proposed for amendment of food sections of the act. These recommendations were endorsed by the Board of Trustees and with its authorization were published in THE JOURNAL.

SERVICE TO PHYSICIANS

The large number of inquiries regularly received by the office of the Committee from physicians indicates a broader recognition of the valuable service the Committee is capable

of giving the medical profession on food questions. The office of the Committee is becoming a repository of such information and furnishes unbiased and authentic reports on request.

APPOINTMENT OF SUBCOMMITTEE TO STUDY RELATIVE HUMAN ANTIRACHITIC VALUES OF VARIOUS TYPES OF VITAMIN D MILKS

Many vitamin D milks fortified by irradiation or by the addition of vitamin D concentrates obtained from cod liver oil have been accepted. These two types of vitamin D milks are considered antirachitic agents when taken in sufficient quantity. Several vitamin D evaporated milks fortified by similar methods have been accepted also, but their status as antirachitic agents has not yet been officially determined. Applications for acceptance of other forms of vitamin D milks, namely milk obtained from herds fed irradiated yeast, and milk fortified with activated ergosterol, have been received and are pending.

The question is now before the Committee of the relative human antirachitic values of these various vitamin D milks. The chairman last May appointed a subcommittee, comprising the three pediatricians of the Committee, to study this problem. The subcommittee has collected all available reports of clinical studies of the various types of vitamin D milks. Owing to the many complex problems involved, the subcommittee was unable to submit its report for consideration by the entire Committee, but this report will probably be available early in 1935. It is the intention of the Committee to publish a report of appraisal of the human antirachitic values of all types of vitamin D milks merchandised. This contribution should be of particular value to physicians, especially pediatricians, the public and the industry.

CONTROL EXERCISED OVER ACCEPTED PRODUCTS AND ADVERTISING

It is a basic requirement of the Committee that accepted foods and promotional advertising be maintained acceptable. This is indispensable to the preservation of the significance of the Committee seal and of acceptance and the prestige of the Committee. For this reason the Committee at the end of 1933 adopted its important rule requiring the submission of all advertising of every character as it issues, and the notification of any changes in labels or composition of accepted foods. Application of this rule began last April. This requirement is something entirely novel to the food industry, as never before has any control of such character and thoroughness been exercised over commercial products and advertising. Although all sponsors of accepted products have signed a written agreement to comply with this rule and are apparently in thorough sympathy with it, it must be recognized that the industry has to adjust itself to this entirely new form of voluntary control. Most sponsors of accepted products, judged by the large volume of submitted advertising, are complying quite satisfactorily with this rule.

A number of companies issuing large volumes of advertising have submitted all copy and have voluntarily stated that the benefits derived from acceptance and the control exercised by the Committee over advertising more than compensate for the nominal expense and inconvenience of submitting the advertising.

CONCLUSION

The members of the Committee have given another year of conscientious service to the economic and nutritional welfare and health of the public. The Committee has at all times displayed a spirit of cordial cooperation with the food industry in its problems of merchandising foods of desired and expected values supported by truthful advertising.

The members of the food industry who have so thoroughly and wholeheartedly cooperated with the Committee by maintaining their accepted products and advertising in conformity with the high standards of the Committee deserve special commendation. Many manufacturers or sponsors of accepted foods at considerable expense or trouble, have discarded improper advertising and given special effort to the development of truthful advertising thus showing their confidence in the principles enunciated by the Committee for the good of the public and the industry. This attitude shown by large and small

manufacturers alike, must gradually but surely lead to a higher order of business in the field of foods and to the establishment of a better recognition of consumer rights, welfare and health.

Conferences with Councils and Editorial Boards

In order that the Board of Trustees might keep in closer touch with the work of the councils and editorial boards of special journals and thereby be enabled to be as helpful as possible in promoting the fine work that is being carried on by these official groups, conferences were held during the year with the Council on Pharmacy and Chemistry and the Council on Physical Therapy and with representatives of some of the editorial boards.

Additional personnel has been provided in the offices of the Council on Pharmacy and Chemistry and of the Council on Physical Therapy, and additional funds have been appropriated for the use of these councils to aid them in meeting the constantly growing demands that are being made on them.

Members of Councils and Committees

Dr Frank H. Krusen of Philadelphia was elected a member of the Council on Physical Therapy for a term of three years.

Dr Stanhope Bayne-Jones of New Haven, Conn., who rendered most devoted and efficient service as a member of the Council on Pharmacy and Chemistry, resigned after he had been made dean of Yale University School of Medicine. Dr J. Howard Brown of Baltimore was made a member of the Council to succeed Dr Bayne-Jones.

Dr George H. Simmons for more than thirty years an active member of the Council on Pharmacy and Chemistry, having expressed a desire to be relieved of active duty, was made an honorary life member by official action of the Council, and Dr Elmer M. Nelson of Washington, D. C., was elected as his successor.

Dr R. L. Sensenich of South Bend, Ind., was made a member of the Committee on Legislative Activities.

Dr Lydia Roberts of Chicago was elected a member of the Committee on Foods to succeed Dr James S. McLester.

Liability Insurance for Members

The Board of Trustees has given its most careful consideration to the resolution, submitted by the delegates from Oklahoma at the Cleveland session, asking that an investigation be made to determine the feasibility of perfecting a plan whereby the American Medical Association could provide liability insurance for members. As the result of a careful study of the various factors involved in this proposal, the members of the Board of Trustees are of the unanimous opinion that it would be inadvisable for the Association to undertake any such enterprise.

Motion Picture of Headquarters

The motion picture portraying some of the important activities in the offices of the Association was shown during the year before various groups in a number of states. The total attendance of physicians at the showing of this picture was in excess of 15,000. The picture has been favorably received and has been highly commended by many individual physicians as a means of acquainting the members of the Association with the character and the scope of the work that is being carried on by councils, bureaus and departments.

Building and Equipment

The building of the Association and all equipment have been maintained in the best possible order, and necessary facilities for maintaining the work of all departments on the highest possible plane of efficiency have been provided.

Much of the Association's work requires highly specialized service and every member of the working personnel has important duties to perform. The Board of Trustees takes pleasure in offering commendation and in acknowledging its grateful appreciation of the faithful and efficient service rendered by the entire body of the Association's employees.

ADDENDA TO REPORT OF BOARD OF TRUSTEES

COMMITTEE ON THERAPEUTIC RESEARCH

The Committee on Therapeutic Research, a standing committee of the Council on Pharmacy and Chemistry, encourages scientific investigations in the field of therapeutics by providing funds for the prosecution of necessary research.

During the year 1934 the committee made thirty-five new grants. A detailed list of these grants together with a list of publications during 1934 and of unexpired grants made before Jan. 1, 1934 will be found in the appendix of this report.

The following is a list of the investigations conducted with the assistance of grants made by the Therapeutic Research Committee, reports of which were published during 1934.

1. Effect of Intravenously Injected Dextrose on the Rate of Propulsion in the Small Intestine. J. P. Quigley and William H. Highstone. *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* 102: 1002 (March 11) 1934.
2. A Study of the Propulsive Activity of a Thiry-Vella Loop of Intestine. J. P. Quigley, W. H. Highstone and A. C. Ivy. *American Journal of Physiology* 108: 151 (April) 1934.
3. Action of Morphine, Papaverine, Atropine, Pilocarpine, Pituitrin, Pitocin and Pitressin on Intestinal Propulsive Activity Determined in the Unanesthetized Dog by the Bolus Method. J. P. Quigley, William H. Highstone and A. C. Ivy. *Journal of Pharmacology and Experimental Therapeutics* 51: 308 (July) 1934.
4. A Simple Adaptation of Kolthoff's Colorimetric Method for the Determination of Magnesium in Biological Fluids. Arthur D. Hirschfelder and Earl R. Serles. *Journal of Biological Chemistry* 104: 635 (March) 1934.
5. Clinical Manifestations of High and Low Plasma Magnesium. Dangers of Epsom Salt Purgation in Nephritis. Arthur D. Hirschfelder. *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* 102: 1138 (April 7) 1934.
6. Effect of Renal Insufficiency upon Plasma Magnesium and Magnesium Excretion After Ingestion of Magnesium Sulphate. Arthur D. Hirschfelder. *Journal of Biological Chemistry* 104: 647 (March) 1934.
7. The Relation of Serum Protein Fractions to Serum Sickness in Rabbits. Lloyd Jones and Moyer S. Fleisher. *Journal of Immunology* 20: 455 (June) 1934.
8. Studies on the Effect of Narcosis on the Rate of Locomotion of Polymorphonuclear Leukocytes in Vitro. Harry Lowenbourg Jr. *American Journal of the Medical Sciences* 188: 472 (Oct.) 1934.
9. The Etiology of Granulopenia (Agranulocytosis) with Particular Reference to the Drugs Containing the Benzene Ring. Roy R. Kracke and Francis P. Parker. *Journal of Laboratory and Clinical Medicine* 19: 799 (May) 1934.
10. The Etiology of Granulopenia (Agranulocytosis) with Particular Reference to Drugs Containing the Benzene Ring. Roy R. Kracke and Francis P. Parker. *American Journal of Clinical Pathology* 4: 453 (Nov.) 1934.
11. The Accumulation of Iron in Tuberculous Areas. IV. The Effect of Ferric Chloride on the Course of Tuberculosis in Reinfected Rabbits. Vally Menkin. *Journal of Experimental Medicine* 60: 463 (Oct. 1) 1934.
12. The Response of the Normal Guinea Pig to the Administration of Liver Extracts. Bernard M. Jacobson. *Science* 80: 211 (Aug. 31) 1934.
13. The Influence of Various Preparations of Lactic Acid and Sugars on the Growth of Transplanted Tumors. II. Mouse Sarcoma 180. I. A. Parfentjev, V. D. Sunitzeff and W. K. Devrient. *American Journal of Cancer* 20: 117 (Jan.) 1934.
14. The Effect of Experimental Dehydration on the Action of Certain Convulsant Drugs. A. H. Maloney. *Archives internationales de pharmacodynamie et de thérapeutique* 47: 284 1934.
15. Barbiturates in Local Anesthetic Toxicity. A. H. Maloney. *Journal of Pharmacology and Experimental Therapeutics* 52: 297 (Nov.) 1934.
16. Magnitude of Urinary Iron Excretion in Healthy Men. Ramon F. Hanzal and Franklin C. Bing. *Proceedings of the Society for Experimental Biology and Medicine* 31: 617 1934.
17. Is the High Basal Metabolic Rate in Hyperthyroidism Due to Thyroxine? J. W. Cavett, Carl O. Rice and J. F. McClendoo. *Science* 80: 19 (July 6) 1934.
18. The Iodine Content of Potatoes. J. F. McClendoo, Earl Barrett and Thomas Canniff. *Biochemical Journal* 28: 1209 1934.
19. On the Use of Ringer-Locke Solutions Containing Hemoglobin as a Substitute for Normal Blood in Mammals. W. R. Amberson, J. Flexner and F. R. Steggerda. A. G. Mulder, M. J. Tendler, D. S. Pankratz and E. P. Laug. *Journal of Cellular and Comparative Physiology* 5: 359 (Dec.) 1934.
20. Oxygen Consumption with Hemoglobin. Ringer, A. G. Mulder, W. R. Amberson, F. R. Steggerda and J. Flexner. *Journal of Cellular and Comparative Physiology* 5: 383 (Dec.) 1934.
21. The Influence of pH upon the Elimination of Hemoglobin by the Perfused Frog's Kidney. M. D. Webster, F. L. Engel, E. P. Laug and W. R. Amberson. *Journal of Cellular and Comparative Physiology* 5: 399 (Dec.) 1934.
22. The Effect of Insulin and Epinephrine on the Amino Acid Content of the Blood of Adrenalectomized Rabbits. Burt L. Davis Jr. and Walton Van Winkle Jr. *Journal of Biological Chemistry* 104: 207 (Feb.) 1934.

During 1934 the following grants were made

Grant 219 Torald Sollmann professor of pharmacology, and Harold N Cole associate clinical professor of dermatology and syphilology Western Reserve University School of Medicine \$100 to investigate the epidemic factor in mercurial salivation

Grant 220 Nora E. Schreiber and Katharine I Henderson Department of Pharmacology Western Reserve University School of Medicine \$200 to investigate the clinical excretion of bismuth and mercury

Grant 221 John G Reinhold, Department of Public Health Philadelphia General Hospital, \$250 to investigate the action of aminoacetic acid in progressive muscular dystrophy

Grant 222 Eugene U Still Department of Physiology University of Chicago School of Medicine \$250 to investigate the changes in the metabolism of the pancreas

Grant 223 Clinton H Thienes professor of pharmacology and Lawrence E Detrick Department of Pharmacology University of Southern California School of Medicine \$200 to investigate withdrawal phenomena in morphine addicted animals

Grant 224 John H Peters, professor of medicine Yale University School of Medicine \$250, to investigate the effects of dinitrophenol

Grant 225 J Murray Luck professor of chemistry Stanford University Calif \$250, to investigate an insulin test for adrenal function

Grant 226 Elaine P Ralli assistant professor of medicine New York University University and Bellevue Hospital Medical College \$250 to investigate the effect of the mouth feeding of carotene on blood carotene

Grant 227 Katharine I Henderson Department of Pharmacology Western Reserve University School of Medicine \$100 to investigate the clinical excretion of mercury and bismuth

Grant 228 Henry G Barbour associate professor of pharmacology and toxicology, Yale University School of Medicine \$250 to investigate metabolism and water exchange in morphine habituation

Grant 229 J F McClendon professor of physiological chemistry University of Minnesota Medical School \$200 to investigate the iodine in the blood of normal and goitrous individuals

Grant 230 Henry B Richardson associate professor of medicine Cornell University Medical College \$250 to investigate female sex hormone therapy

Grant 231 William R Amberson professor of physiology University of Tennessee College of Medicine \$100 to investigate hemoglobin perfusion fluids

Grant 232 George R Cowgill associate professor of physiological chemistry Yale University School of Medicine \$250 to investigate the heart in vitamin B deficiency

Grant 233 Norman A David assistant professor of pharmacology West Virginia University School of Medicine \$100 to investigate the effect of carbarsone and other related para positioned amine grouped organic arsenicals on the optic nerve

Grant 234 Read M Ellsworth Johns Hopkins Hospital \$150 to investigate the physiology of the parathyroid glands

Grant 235 Owen S Gibbs professor of physiology Georgetown University School of Medicine \$75 to investigate the effects of continuous small doses of substances injected into the arterial supply of an organ with especial reference to secretory glands

Grant 236 Charles W Greene professor of physiology and pharmacology University of Missouri School of Medicine \$100 to investigate the pharmacology of the so-called specific coronary dilator drugs

Grant 237 Louis N Katz physiologist and director of cardiovascular research Nelson Morris Memorial Institute for Medical Research Michael Reese Hospital Chicago \$100 to investigate the action of drugs on the coronary circulation

Grant 238 Roy R Kracke professor of pathology Emory University School of Medicine \$250 to investigate the effect of the oxidation products of amidopyrine and related drugs on the leukocyte counts of rabbits

Grant 239 John R Marlin director and professor of physiology Department of Vital Economics University of Rochester School of Medicine, \$100 to investigate the absorption of insulin from the alimentary canal

Grant 240 Kenneth W Thompson resident surgeon Peter Bent Brigham Hospital Boston \$250 to investigate the effects of the thyroid stimulating hormone pituitary its relationship to other substances in the possible control of hyperthyroidism

Grant 241 George E. Wakerlin associate professor of physiology and pharmacology, University of Louisville School of Medicine \$200 to investigate hematopoiesis

Grant 242 Abraham White Department of Physiological Chemistry Yale University School of Medicine \$100 to investigate the metabolism of the essential amino acids cystine methionine and histidine

Grant 243 Fred C Koch chairman of the Department of Physiological Chemistry and Pharmacology University of Chicago \$250 to investigate the antirachitic potency of irradiated sterols other than ergosterol

Grant 244 Bernard M Jacobson Massachusetts General Hospital Boston \$200 to investigate liver extracts

Grant 245 Carl J Wiggers professor of physiology Western Reserve University School of Medicine \$250 to investigate the usefulness of drugs in coronary thrombosis

Grant 246 Treat B Johnson Sterling professor of chemistry Yale University \$250 to investigate the pharmacologic action of some pyridine derivatives in relation to their chemical constitution

Grant 247 Arthur W Grace Department of Medicine Cornell University Medical College \$250 to investigate the use of antimonial compounds in the treatment of lymphogranuloma inguinale

Grant 248 Fred C Koch chairman of the Department of Physiological Chemistry and Pharmacology University of Chicago \$250 to investigate the testis hormone

Grant 249 J Percy Baumberger associate professor of physiology Stanford University \$200, to investigate the occurrence and oxidation reduction potential of pigments in tumor cells

Grant 250 A R McIntyre, professor of pharmacology University of Nebraska College of Medicine, \$100, to investigate the effects of the digitalin bodies on the metabolism of dextrose by the cardiac musculature

Grant 251 Bernard Fantus professor of therapeutics University of Illinois College of Medicine \$100, to investigate the titration of the antitoxic value of serum of patients who have received tetanus antitoxin

Grant 252 Frederick D Weidman professor of dermatologic research University of Pennsylvania School of Medicine \$100 to investigate the causes of human blastomycosis

Grant 253 Katharine I Henderson Department of Pharmacology Western Reserve University School of Medicine \$300, to investigate the excretion of bismuth

The following grants were issued before Jan. 1, 1934 In some cases the grant has expired and an unexpended balance remains, or the work is not yet completed or a report not yet published

Grant 102 C W Greene professor of physiology and pharmacology University of Missouri Department of Physiology \$250 to investigate the distribution of nitrous oxide and oxygen in the blood during anesthesia

Grant 119 Nicholas Kopeloff research associate in bacteriology New York State Psychiatric Institute and Hospital \$100 to investigate bacillus scitophilus milk for the prevention and treatment of summer diarrhea in babies

Grant 143 Cleveland J White MD 104 South Michigan Avenue Chicago \$150 to investigate the local general and prophylactic aspects of superficial fungus diseases of the skin

Grant 152 C W Greene professor of physiology and pharmacology, University of Missouri Department of Physiology \$300 to investigate the reaction of the coronary system to drugs

Grant 164 E L Jackson associate professor of pharmacology Emory University School of Medicine \$200 to investigate the antagonism between sodium barbital and insulin

Grant 166 Jean Oliver professor of pathology Hoagland Laboratory Long Island College of Medicine, \$200 to investigate experimental nephritis in the frog

Grant 171 Ernest C Dickson professor of Department of Public Health and Preventive Hygiene Stanford University School of Medicine \$250 to investigate therapeutic procedures against coccidioid granuloma

Grant 192 Carl J Wiggers professor of physiology Western Reserve University School of Medicine \$250 to investigate the effect of drugs on the coronary circulation in intact dogs

Grant 194 Sarah A Riedman Columbia University College of Physicians and Surgeons \$200 to investigate the effect of a high fat or ketogenic diet on the susceptibility of animals to convulsions of experimental origin

Grant 199 Henry G Barbour associate professor of pharmacology and toxicology Sterling Hall of Medicine, Yale University \$250 to investigate the effects of metabolism and water exchange of long continued administration of morphine

Grant 200 Walter Bauer Massachusetts General Hospital the Robert W Lovett Memorial Foundation of the Harvard Medical School \$250 to investigate the anatomy and physiology of normal joints with special reference to rheumatoid arthritis

Grant 201 George R Cowgill associate professor of physiologic chemistry Sterling Hall of Medicine Yale University \$250 to investigate vitamin B in relation to morphine addiction

Grant 202 Charles M Gruber professor of pharmacology Jefferson Medical College of Philadelphia \$200, to investigate the effects of drugs on Bell's muscle trigon and fundus of the urinary bladder and of dilaudid on the intestine of unanesthetized dogs

Grant 204 E B Krumbhaar professor of pathology McManes Laboratory of Pathology University of Pennsylvania School of Medicine \$100 to investigate leukocyte attraction

Grant 207 Valy Menkin, Department of Pathology Harvard Medical School, \$200 to investigate inflammation and tuberculosis in relation to immunity

Grant 209 V C Myers professor of biochemistry and F C Bing Department of Biochemistry Western Reserve University School of Medicine \$250 to investigate iron metabolism

Grant 210 C I Reed associate professor of physiology University of Illinois College of Medicine \$200 to investigate the use of viosterol 10 000 X in seasonal hay fever

Grant 211 Samuel R M Reynolds Department of Physiology and Pharmacology Long Island College of Medicine \$150 to investigate the identification and standardization of progesterin

Grant 212 William C Rose professor of physiologic chemistry University of Illinois \$375 to investigate the isolation of an unknown dietary essential present in proteins

Grant 213 Richard W Whitehead professor of physiology and pharmacology University of Colorado School of Medicine and Hospitals \$200 to investigate the influence of the administration of adrenal cortex extract on the resistance to bacterial toxins

Grant 214 E. A Park professor of pediatrics and J A Pierce Johns Hopkins University School of Medicine \$200 to investigate the reaction of cartilage

Grant 215 W R Amberson professor of physiology University of Tennessee College of Medicine \$250 to investigate hemoglobin perfusion fluids

Grant 217 Henry B Richardson professor of medicine Cornell University Medical College \$250 to investigate sex hormone therapy

Grant 218 O W Barlow assistant professor of pharmacology Western Reserve University School of Medicine \$150 to investigate the effects of a series of analeptics against pentobarbital tribrom-ethanol and chloral hydrate

Report of the Committee on Scientific Research for 1934

During the year, sixty-three formal applications have been received. Thirty-seven awards have been made, the amount awarded is \$13,128.05. Thirty applications have been declined, one was withdrawn, and five are under consideration. The new grants are for the support of research in various fields of medicine. In all cases the money has been paid to the financial officer of the institution with which the grantee is connected. The grants are disbursed on requisition by grantees and full accounts are kept of the disbursements. Recent reports from the grantees indicate that their work as a rule is making good progress. The final or practically final results of work under forty-eight grants, mostly prior to 1934 have been published or are in actual course of publication; the files in these grants have been closed. The results of work under eleven grants prior to 1934 are in the course of preparation for publication. In the case of twenty-nine grants prior to 1934 active work is still in progress but in several cases reports on results have been published. Refunds amounting to \$304.22 have been made from grants.

The committee begs leave to recommend that as nearly as possible the same appropriation be made for 1935 as for 1934 namely, \$12,550 for grants in aid of medical research and \$1,200 for the expenses of the committee.

The financial statement for 1934 is presented also brief accounts of the grants pending at the end of 1933 and a list of the grants made in 1934.

GRANTS OF COMMITTEE ON SCIENTIFIC RESEARCH NEW GRANTS—1934

Grant 310 Lay Martin Johns Hopkins University \$150 for study of gastric juice

Grant 311 M G Seelig Barnard Free Skin and Cancer Hospital St Louis \$250 for study of radiosensitivity of neoplasms

Grant 312 C A Hellwig St Francis Hospital Wichita Kan \$100 for study of thyroid function in experimental colloid goiter

Grant 313 L A Emge Stanford University School of Medicine \$300 for study of relation between pregnancy and tumor growth

Grant 314 Bernard Portis Michael Reese Hospital, Chicago \$300 for study of immune reactions of Flexner Jobling rat tumor

Grant 315 Phillips Thygeson University of Iowa \$300 for study of virus diseases of the eye

Grant 316 Harry Goldblatt Western Reserve University \$150 for completion of study of hypertension in dogs

Grant 317 M D Overholser University of Missouri \$300 for study of experimental growths in genital tract of monkeys and relation of anterior hypophysis to diabetes

Grant 318 Charles J Sutro Hospital for Joint Diseases New York \$300 for work with the fluorescent microscope

Grant 319 J Paul Visscher Western Reserve University \$1,000 for work on a chemical test for pregnancy

Grant 320 M L Tainter Stanford University School of Medicine \$1,000 for study of metabolic actions of dinitrophenol in man

Grant 321 Ernest C Faust Tulane University \$800 for completion of study on Strongyloides stercoralis

Grant 322 W J Nungester Northwestern University Medical School \$130 for study of the effect of mucin on infection

Grant 323 Edward J Van Lier West Virginia University \$300 for study of the effect of anoxemia on smooth muscle

Grant 324 William deB MacNider University of North Carolina \$250 for study of artificial circulation in the kidney

Grant 325 Timothy Leary Office of Medical Examiner Boston \$300 for expenses of publication of results of work under grant 22 1931

Grant 326 Rachel E Hoffstadt, University of Washington, \$200 for study of protein and carbohydrate fractions of *Staphylococcus aureus*

Grant 327 Timothy Leary, Office of Medical Examiner Boston, \$300 for study of cholesterol atherosclerosis in rabbits

Grant 328 W R Tweedy Loyola University School of Medicine, \$300 for further study on parathyroid hormone

Grant 329 Jane Sands Robt Syracuse University \$300 for further study of individual cardiac muscle.

Grant 330 Alexander S Wiener Jewish Hospital of Brooklyn, \$150 for study of agglutinogens and agglutinins of human blood and their heredity

Grant 331 John R Murlin University of Rochester Medical School, \$900 for study of the testis hormone

Grant 332 W T Dawson University of Texas School of Medicine, \$100 for study of the cinchona alkaloids

Grant 333 Arthur J Geiger and Louis S Goodman Yale University \$250 for study of antineoplastic principle.

Grant 334 H A Kemp W H Moursand and H E Wright, Baylor University \$267.05 for study of relapsing fever in Texas.

Grant 335 Erwin Brand and G F Cahill New York State Psychiatric Institute and Hospital \$200 for further work on cystinuria.

Grant 336 Charles H Frazier Hospital of University of Pennsylvania \$751 for study of autonomic representation of the urinary bladder in the cerebral cortex and in the hypothalamus

Grant 337 James L O Leary Washington University, \$245 for investigation of Loven reflexes

Grant 338 W W Brandes Baylor University \$150 for study of the effect of acidosis on antibodies and resistance to infection

Grant 339 W T Dawson University of Texas School of Medicine \$100 for study of relation between chemical constitution and physiologic action of cinchona alkaloids

Grant 340 Louis S Goodman and Arthur J Geiger Yale University \$200 for further study of antineoplastic principle.

Grant 341 Ludwig A Emge Stanford University School of Medicine \$500 for study of pregnancy and tumor growth

Grant 342 S S Lichtman Mount Sinai Hospital New York \$400 for study of bile salt metabolism in liver disease.

Grant 343 John Guttman Post Graduate Medical School and Hospital \$400 for study of relation between electrical disturbances in cochlea and the sensation of hearing

Grant 344 Paul L Day and W C Langston University of Arkansas School of Medicine \$300 for study of effect of withdrawal of vitamin G from diet of monkeys

Grant 345 Emile Holman Stanford University School of Medicine \$400 for study by Frederic Fender of prolonged stimulation of the nervous system

Grant 346 William Antopol Mount Sinai Hospital New York, \$750 for study of the relationship of acetylcholine to carbohydrate metabolism

STATE OF WORK UNDER PREVIOUS GRANTS

1 COMPLETED DURING THE YEAR

Grant 163 1929 \$750 to George Hermann Tulane University School of Medicine for the study of problems of the circulation (refund \$17.80). The work under this grant has been carried on to completion by Roy H Turner assistant professor of experimental medicine Tulane University. Turner Roy H and Sodeman W A. Repeated Determinations of Pulse Velocity in Normal Individuals. *Proc Soc Exper Biol & Med* 31 831 1934. Turner Roy H. Studies on the Physiology of the Peripheral Vessels. I. Instruments and Methods to be offered for publication in *Journal of Clinical Investigation*. Turner Roy H and Sodeman, W A. Studies on the Physiology of the Peripheral Vessels. II. Repeated Determinations of Pulse Wave Velocity in Normal Individuals and in Those Suffering from Hypertension or Arteriosclerosis to be offered for publication in *Journal of Clinical Investigation*.

Grant 167 1929 \$500 to Hans Jensen Johns Hopkins University for aid in the chemical and physiologic study of toad poisons (refund, \$60.81). Jensen Hans and Chen K K. Chemical Studies on Toad Poisons. *J Biol Chem* 87: 741 and 755 1930. Jensen Hans. *Science* 75: 53 1932. Jensen Hans and Evans E A Jr. *J Biol Chem*. 104 307 1934.

Grant 181 1930 Erwin Brand New York State Psychiatric Institute and Hospital \$700 for research in cystinuria (refund \$366.67). See grant 302 1933.

Grant 182 1930 Icie G Macy Merrill Palmer School Detroit \$500 for a study of vitamins A and B in human breast milk. Donelson Eva and Macy Icie G. Human Milk Studies. XI. Vitamin G (B₆) Content of Mixed Milk. *Am J Physiol* 100 420 1932. Human Milk Studies. XII. The Vitamin B and Vitamin G Content Before and During Maternal Consumption of Yeast. *J Nutrition* 7: 231 1934. McCosh Sylvia S. Macy Icie G. Hunscher Helen A. Erickson Betty N and Donelson Eva. Human Milk Studies. XIII. Vitamin Potency as Influenced by Supplementing the Maternal Diet with Vitamin A. *ibid* 7 331 1934.

Grant 183 1930 Robert W Hegner Johns Hopkins University \$1,500 for study of host-parasite relations in man in continuation of work under previous grants 101 (C A Brant Fund) 1926 125 1927 and 154 1929. For list of articles on results of work under this grant see the report of the committee for 1933. New articles: Hegner Robert

The Effects of a High Vegetable Protein Diet on the Trichomonad Flagellates of Rats *Am J Trop Med* 8:535 1933 Effects of Environmental Changes and Disinfectants and Antiseptics on Trichomonas Hominis in Culture and in Feces, *Am J Hyg* 10:22 1934 Specificity in the Genus Balantidium Based on Size and Shape of Body and Macronucleus with Descriptions of Six New Species, *ibid* 19:38 1934 Intestinal Protozoa of Chimpanzees *ibid* 10:480 1934

Grant 189, 1930 Ralph H Major University of Kansas Lawrence \$500 for study of depressor substances in the brain liver and pancreas Major Ralph H, Nannings J B and Weber C J A Comparison of the Properties of Certain Tissue Extracts Having Depressor Effects *J Physiol* 70:487, 1932 Weber C J Nannings J B and Major Ralph H Isolation of a Crystalline Depressor Substance from the Brain *Proc Soc Exper Biol & Med* 30:513 1933

Grant 194 1930 C H Thienes University of Southern California Los Angeles \$500 for study of the relationship between the myenteric plexus and ganglions and the mesenteric nerves Shulter Lillian and Thienes C H Analysis of the Actions of Cocaine on Excised Smooth Muscles, *Proc Soc Exper Biol & Med* 28:994 1931 Hendricks

Balance on hand

\$ 6 404 70

Max D and Thienes C H A Pharmacologic Study of the Inhibitory Mesenteric Nerves to the Intestines *ibid* 28 993 1931 See grant 236 1932

Grant 201 1931 J H Black Baylor University College of Medicine \$100 for study of the relation of certain pollen fractions (refund \$34 80) Black J H, and Shelmure B The Urinary Protease in Allergy *J Allergy* 5:373 1934

Grant 202 1931 James T Case and C A Aldrich Evanston Hospital Evanston Ill \$250 for roentgenologic and clinical study of the thymus Case J T The Present Status of the Roentgen Diagnosis and Therapy of Persistent Thymus to be offered for publication in *American Journal of Diseases of Children*

Grant 210 1931 Harold E Himwich Yale University School of Medicine \$500 for a study of fat metabolism in diabetes Himwich Harold E and Spiers, M A The Degree of Saturation of Blood Fats Mobilized During Diabetes *Proc Soc Exper Biol & Med* 29 235 1931 Brockett Susan H Spiers Mary A, and Himwich Harold E The Lipoid Components of the Lymph of the Thoracic Duct of the Dog *Am J Physiol*

Grant 220 1931 David Polowe Paterson N J and Memorial Hospital New York \$100 for a study of the specific gravity of the blood in human cancer Polowe David The Specific Gravity of the Blood in Human Cancer *J Lab & Clin Med* 19:983 1934

Grant 225 1931 R S Cunningham Vanderbilt University, Nashville Tenn. \$500 toward a study of the cellular reactions in experimental syphilis with respect to the effects of treatment. Cunningham R S and associates The Cellular Pathology of Experimental Syphilis as Studied by the Supravital Method *Am J Syph* 17:515 1933 See Grant 261 1932

Grant 226 1931 Warren C Hunter University of Oregon Medical School \$100 for a study of the effect of cinchophen on the liver of the dog (refund \$36 07) Hunter W C, and Snyder George A C Experimental Attempt to Produce Hepatic Damage in the Dog by Feeding of Cinchophen *West J Surg Obst & Gynec* 42 288 1934

Grant 229 1931 Timothy Leary, Office of the Medical Examiner, Boston \$810 toward a study of the effect of alcohol and insulin on the deposition of cholesterol in the animal body Leary Timothy Human Coronary and Experimental Rabbit Atherosclerosis A Comparison of Lesions *New England J Med* 200 1132 1933 Experimental Atherosclerosis in Rabbit, *Arch Path* 17 453 1934

Grant 230 1932 Alexander S Wiener Jewish Hospital of Brooklyn \$50 for a study of agglutination N See grant 296 1933

Grant 235 1932 E A Smith Iowa State College \$100 for study of the effects of illuminating gas and amyl acetate on the rat (See grant 297 1933) Mack, Lillian and Smith, E A Methylene Blue in Illuminating Gas Poisoning *Proc Soc Exper Biol & Med* 31 1031 1934

Grant 236, 1932 C H Thienes University of Southern California \$400 for studies on the relation of the mesenteric nerves to the myenteric ganglions and plexuses (See grant 194 1930) Refund \$17 95 Newman Milton and Thienes C H On the Sympathetic Innervation of Guinea Pig Intestine *Am J Physiol* 104:113 1933 Hockett A J Newman Milton and Thienes C H The Reciprocal Activity of the Muscle Coats of the Guinea Pig Small Intestine *Arch internat pharm et therap* 40:363 1933

Grant 246 1932 W C Langston and Paul L Day University of Arkansas \$400 for a study of vitamin G deficiency in the monkey with special reference to cataract Day Paul L Langston William C and Shukers Carroll F Leukopenia and Anemia in the Monkey Resulting from Vitamin Deficiency to be published in *Journal of Nutrition*

Grant 248 1932 Helen C Coombs New York Homeopathic Medical College and Flower Hospital \$575 for work on the relationships between epilepsy and tetany Coombs Helen C Combined Effects of Drugs and Electrical Excitation of Cortical Motor Area in Cats *Proc Soc Exper Biol & Med* 30 1 1932 Coombs Helen C and Searle Donald S Calcium Phosphorus of the Blood Serum During Cerebral Anemia *Am J Physiol* 105 1933 Coombs Helen C Searle D S and Pike F H The Changes in the Concentration of Inorganic Calcium and Phosphate During Convulsions of Experimental Origin in Cats, Before and After Thyroparathyroidectomy With and Without Bromide Therapy *Am J Psychiat* 13 761 1934

Grant 249 1932 Arthur H Smith Yale University \$350 for a study of the acid base balance and the osmotic pressure of the blood of stunted albino rats Brooke R O Smith A H and Smith P K Inorganic Salts in Nutrition VII Change in Composition of Bone of Rats on a Diet Poor in Inorganic Constituents *J Biol Chem* 104:141 1934

Grant 250 1932 S S Lichtman Mount Sinai Hospital New York \$400 for work on a method of estimating bile salts in body fluids (See grants 271 1932 and 306 1933)

Grant 253 1932 Willard O Thompson Rush Medical College Chicago \$250 for study on the influence of thyroxine on the toxic effects of arsenamine and acetanilide (See grant 268 1932)

Grant 255 1932 Max Wisnofsky Jewish Hospital of Brooklyn \$100 for work on problems in carbohydrate metabolism Wisnofsky Max Absorption of Dextrose from the Human Gastro-Intestinal Tract, *J Lab & Clin Med* 19:1286 1934 Wisnofsky Max and others The Influence of Dinitrophenol on Carbohydrate Metabolism *Arch Int Med* Wisnofsky Max The Effect of Equivalent Amounts of Dextrose and Starch on Glycemia and Glycosuria in Diabetes to be published in *American Journal of the Medical Sciences*

Grant 261 1932 R S Cunningham, Vanderbilt University \$300 for work on the effects of certain colloidal solutions on experimental syphilis (refund \$1 49) Cunningham R S and associates The Effect of Trypan Blue on Experimental Syphilis in the Rabbit *Am J Syph* 17:522 1933 The Effect of Lecithin on Experimental Syphilis in the Rabbit *ibid* 18:333 1934 Lowenstein L The Leukocytes in Early Acute Experimental Syphilis in Rabbits *Am J Syph & Neurol* 19 39 1935

Grant 267 1932 M S Dooley (Jane Sands Robb) Syracuse University \$200 for study of the blood supply of individual heart muscle bundles

Robb Jaoc Saods Evidence for Characteristic Modifications of the Electrocardiogram Produced by Lesions of Ventricular Muscle Bands *Proc Soc Exper Biol & Med* 31:311 1933 Progressive Muscular Anemia in the Heart of a Dog *ibid* 31:761 1934 The Structure of the Mammalian Ventricle *M & Prof Women's J* 41:65 1934 An exhibit illustrating the individual cardiac muscles was awarded a certificate of Merit, Class 1 Scientific Exhibit American Medical Association 1934

Grant 268 1932 W O Thompson Rush Medical College \$250 for study of relation between thyroxine and glutathione oxidation system Thompson, W O and others Effect of Alkali on the Absorption of Thyroxine from the Gastrointestinal Tract *Arch Int Med* 52:809 1933 Thompson W O and others The Effect of Dimethyltyrosine on the Basal Metabolism in Myxedema *J Clin Investigation* 13:29 1934 Thompson W O and others The Effect of Various Compounds of Thyroxine on the Basal Metabolism *Endocrinology* 18:228 1934

Grant 270 1932 Edwin F Hirsch St. Luke's Hospital Chicago \$500 for determination of copper and active iron in tissues in infection and toxemia Locke A Roshash D O and Shinn L E Copper and Iron in the Metabolism of Cellular Metabolism *J Infect Dis* 54:51 1934

Grant 271 1932 S S Lichtman Mount Sinai Hospital New York \$75 to complete methods for estimating bile salts in normal body fluids (See grants 250 1932 and 306 1933)

Grant 272 1932 Joseph L Donnelly University of Cincinnati \$750 for work on the coagulation of biologic materials Donnelly J L On the Physiological Effects of Radio Waves *Science* 78:290 1933

Grant 274 William C. Rose University of Illinois Urbana \$300 for study of unknown dietary essential in casein Caldwell C T, and Rose W C Feeding Experiments with Mixtures of Highly Purified Amino Acids IV The Supplementing Effect of Casein Fractions Obtained by the Carbamate Procedure *J Biol Chem* 107:45 1934 Caldwell C T and Rose W C Feeding Experiments with Mixtures of Highly Purified Amino Acids *ibid* 107:57 1934

Grant 275 1933 John Guttman Post Graduate Medical School and Hospital New York \$400 for study of electric current produced by cochlea on stimulation by sound Guttman John Electrical Disturbances in the Cochlea Produced by Sound *Laryngoscope* 1933 Guttman John and Barrera S E Persistence of Cochlear Electrical Disturbance on Auditory Stimulation in the Presence of Cochlear Ganglion Degeneration *Am J Physiol* 100:704 1934

Grant 283 1933 Philip B Armstrong Cornell University Medical College \$150 for study of drug action in relation to enervation of the heart Armstrong Philip B The Role of the Nerves in the Action of Acetylcholine on the Embryonic Heart to be submitted to *Journal of Physiology*

Grant 285 1933 M G Seelig Barnard Free Skin and Cancer Hospital St. Louis \$200 for a study of the carcinogenic action of dibenzanthracene 1 2 5 6 and of scarlet red Refund \$468 Seelig M G Dibenzanthracene 1 2 5 6 as a Carcinogenic Agent *Am J Cancer* 20:827 1934

Grant 288 1933 James L O Leary Washington University \$175 for work on the nervous mechanisms controlling blood pressure. O Leary J L Heinbecker P and Bishop G F The Fiber Constitution of the Depressor Nerve of the Rabbit *Am J Physiol* 100:274 1934 Bishop G H Heinbecker P and O Leary James The Significance of Frequency Number of Impulses and Fiber Size in Vasomotor Responses to Vagus and Depressor Nerve Stimulation in the Rabbit *ibid* 100:409 1934

Grant 289 1933 Harry J Deuel Jr University of Southern California \$300 for further study of the sexual variation in carbohydrate metabolism Deuel H J Jr and others The Sexual Variation in Carbohydrate Metabolism III The Comparative Glycogen and Fat Content of the Liver and Muscles of Rats and Guinea Pigs *J Biol Chem* 104:519 1934 Gruenewald C F Cutler C H and Deuel Harry J Jr The Sexual Variation in Carbohydrate Metabolism V The Metabolism of Diacetic Acid in Normal and Castrated Male and Female Rats With and Without Testes *ibid* 105:35, 1934

Grant 290 1933 Harry Goldblatt, Western Reserve University \$150 for study of experimental hypertension in dogs (See grant 316, 1934)

Grant 291 C Alexander Hellwig St. Francis Hospital Wichita, \$50 for work on the thyroid gland and on thyrotropic substance in human urine Hellwig C A Morphographic and Experimental Studies on the Etiology of Goiter *West J Surg Obst & Gynec* 41:453, 1933 Hellwig C A Experimental Colloid Goiter *Endocrinology* 18:197 1934

Grant 292 1933 Ludwig A Emge Stanford University School of Medicine \$200 for study of transplantable benign tumors during pregnancy Emge L A and Wulff L M R The Influence of Pregnancy on Experimental Tumor Growth in the White Rat Volumetric Studies on Adenofibroma and Fibroma *West J Surg Obst & Gynec* 42:45, 1934

Grant 293 1933 Arthur Grollman Johns Hopkins University \$200 for study of the effects of adrenal cortex extract Howard E and Grollman Arthur The Effect of Extracts of the Adrenal Cortex on Growth and the Reproductive System of Normal Rats with Particular Reference to Intersexuality *Am J Physiol* 107:480 1934 Grollman Arthur and Firor W M Studies on the Adrenal IV The Oral Administration of the Adrenal Cortical Hormone and the Use of Fresh Glands Therapeutically *Bull Johns Hopkins Hosp* 54:216 1934

Grant 295 1933 W R Tweedy Loyola University School of Medicine \$350 for chemical studies on parathyroid hormone. (See also grants 143 and 146 1928 grant 216 1931 and grant 328 1934) I Schonr, I Tweedy W R and McJunkin F A The Effect of Experimental Hyperparathyroidism on the Incisor of the Rat *Proc Soc Exper Biol &*

Med 31:517 1934 The Effect of Single and Multiple Doses of Parathyroid Hormone on the Calcification of the Dentin of the Rat Incisor *Am J Path* 10:321 1934 Tweedy W R Bell W P, and Vicens-Rio C Further Chemical Studies on a Parathyroid Hormone, *J Biol Chem*

Grant 296 1933 Alexander S Wiener Jewish Hospital of Brooklyn, \$100 for work on agglutinogens M and N Refund, \$23.13 (See grant 230 1932) Wiener, Alexander S and Rothberg Sidney Heredity of the Subgroups of Group A and Group AB *Human Biol* 5:577 1933, Wiener A S Zinsher R and Selkove J The Agglutinogens M and N of Landstelter and Levine *J Immunol* 27:355 1934 Wiener A S Heredity of the Agglutinogens M and N IV Additional Theoreticostatistical Considerations to be published in the *Human Biology*

Grant 298 1933 Lewis H Hitzrot Philadelphia General Hospital \$100 for study of the therapeutic effect of alternate negative and positive pressure Hitzrot Lewis H and Landis Eugene M The Clinical Value of Alternating Suction and Pressure in the Treatment of Advanced Peripheral Vascular Disease to be published in *American Journal of the Medical Sciences*

Grant 300 J M Wolfe Vanderbilt University \$100 for study of histology of anterior hypophysis Ellison E T and Wolfe, J M The Effect of Castration on the Anterior Hypophysis of the Female Rat, *Endocrinology* 18:555 1934 Wolfe J M Ellison E T and Rosenfeld L Morphological Studies on the Anterior Pituitaries of Mature Female Rats Receiving Injections of Pregnancy Urine Extracts, *Anat Rec* 60:357, 1934 Wolfe Jack Morris Phelps Dons and Cleveland Rucker The Anterior Hypophysis of the Rabbit During Oestrus and Pseudopregnancy *Am J Anat* 55:363 1934 Wolfe, J M Morphological Comparison of Anterior Pituitaries of Normal Castrated Female Rats and Those Receiving Injections of Pregnancy Urine Extracts *Proc Soc Exper Biol & Med* 32:184 1934 Wolfe J M Comparative Quantitative Effects of Castration in Mature and Immature Female Rats *ibid* 32:186 1934 Campbell, Mary Wolfe J M and Phelps Doris Effect of Feeding Thyroid on Anterior Hypophysis of the Female Albino Rat *ibid* 32:205 1934 Wolfe, J M Anterior Pituitaries of Infantile Female Rats Receiving Injections of Pregnancy Urine Extract *ibid* 32:214 1934 Wolfe, J M Reaction of the Anterior Pituitaries of Immature Female Rats to Injection of Pregnancy Urine Extracts *J Physiol* 110:159 1934 Wolfe, J M The Normal Level of the Various Cell Types in the Anterior Pituitaries of Mature and Immature Rats and Further Observations on Cyclic Histologic Variations *Anat Rec* 61:321 1935

Grant 302 1933 Erwin Brand and G F Cahill New York State Psychiatric Institute and Hospital \$250 for research on cystinuria. (See grant 181 1930) Brand Erwin Cahill George F, and Harris, M H Metabolism of Various Sulphur Compounds in Cystinuria, *Proc Soc Exper Biol & Med* 31:348 1933 Brand Erwin and Cahill George F Further Studies on Metabolism of Sulphur Compounds in Cystinuria *ibid* 31:1247 1934 Brand Erwin Congenital Anomalies of Metabolism with Special Reference to Cystinuria and Myopathies *Bull New York Acad Med* 10:289 1934

Grant 306 1933 S S Lichtman, Mount Sinai Hospital New York \$350 for further study on estimation of bile salts in body fluids. (See grants 250 and 271 1932) Lichtman S S A New Procedure for the Estimation of Bile Salts in Body Fluids Based on Bile Salt Hemolysis, *J Biol Chem* 107:717 1934

Grant 307 1933 E K. Marshall Jr, Johns Hopkins University \$200 for study of the action of iodine compounds on experimental exophthalmic goiter in guinea pigs Friedgood H B The Iodine Remission in Experimental Exophthalmic Goiter of Guinea Pigs *J Pharmacol & Exper Therap*

Grant 316 1934 Harry Goldblatt Western Reserve University \$150 for study of hypertension in dogs (See grant 290 1933) Goldblatt, Harry and others Studies on Experimental Hypertension I The Production of Persistent Elevation of Systolic Blood Pressure by Means of Renal Ischemia *J Exper Med* 59:347 1934

Grant 325 1934 Timothy Leary Boston \$300 for expenses of publication of results of work under grant 229 1931 Refund \$79.48. Leary Timothy Experimental Atherosclerosis in the Rabbit *Arch. Path* 17:453 1934

2 INCOMPLETE

A Work under the grant completed account rendered of expenses but results not published fully

Grant 118 1927 \$1000 to Edward Reynolds and E A Hooton, Harvard University for study of the mechanism of erect posture

Grant 133 1928 \$715 to F Lowell Dunn University of Nebraska, for spectrophotometric analysis of biologic fluids Dunn F Lowell A Cylindrical Rotating Sector Photometer, *Rev Scient Instruments* 2:807 1931 Refund \$53.14

Grant 203 1931 W J Merle Scott University of Rochester School of Medicine and Dentistry \$300 toward a study of the role of the adrenal cortex in pyogenic infections (refund \$64.22) Scott W J Merle and others The Influence of Adrenal Cortex Extract on the Resistance to Certain Infections and Intoxications *Endocrinology* 17:529 1933

Grant 209 1931 and grant 243 1932 Wilbur A Selle University of Texas School of Medicine \$400 for a study of the carbohydrate metabolism in its relation to the growth of tumors

Grant 233 1932 Detlev W Bronk, University of Pennsylvania School of Medicine \$550 for studies on the nervous regulation of the circulation Bronk D W and Ferguson L K Impulses to Cardiac Sympathetic Nerves *Proc Soc Exper Biol & Med* 30:339 1932

Grant 259 1932 Daniel A. McGinty Emory University \$150 for study of lactic acid dextrose and oxygen absorption and carbon dioxide production by heart muscle (refund \$125.49)

Grant 265 1932 S W Ranson, Northwestern University, Chicago \$400 for study of structure and function of cutaneous nerves in man
Ranson S W Cutaneous Sensation *Science* 78:395 1933 (See grant 299 1933)

Grant 273 1933 Gregory Schwartzman Mount Sinai Hospital New York \$400 for study on antibodies to Rous sarcoma agent by local skin reactivity

Grant 284, 1933 Helen C Coombs New York Homeopathic Medical College and Flower Hospital \$600 for study of the bromide treatment of experimental convulsions

Grant 299 1933 S W Ranson Northwestern University \$250 for study of cutaneous nerves in man (See grant 265 1932)

Grant 304 Frederic A Gibbs Boston City Hospital Boston \$200 for work on the convulsive center in the cat brain

B Active work still in progress

Grant 162 1929 \$100 to J P Simmonds Northwestern University Medical School for a study of the action of cinchophen and its derivatives on the liver Churchill T P and Van Wagoner F H Cinchophen Poisoning *Proc Soc Exper Biol & Med* 28:581 1931 Vao Wagoner, F H and Churchill T P Production of Gastric and Duodenal Ulcers in Experimental Cinchophen Poisoning J A M A 99 1859, 1932 Churchill T P and Manshardt D O Experimental Production of Gastric and Duodenal Ulcers in Dogs in Cinchophen Poisoning *Proc Soc Exper Biol & Med* 30 825 1933 Van Wagoner F H and Churchill T P Production of Gastric and Duodenal Ulcers in Experimental Cinchophen Poisoning of Dogs *Arch Path* 14:860 1932

Grant 174 1930 Alfred R Ross College of Medical Evangelists Loma Linda Calif, \$1455 for study of hay fever pollen in the Southwest.

Grant 179 1930 George T Pack Memorial Hospital New York \$300 for a study of certain clinicopathologic problems of melanoma (See grant 231, 1932)

Grant 198 1931 Gilbert Dalldorf (Robert L Dickinson) Grasslands Hospital Valhalla N Y \$200 for a study of the human uterus by casts and in other ways (refund \$94 00)

Grant 218 1931 Clayton J Lundy Rush Medical College Chicago \$1000 toward making animated motion pictures of the actions of the heart in health and in disease. See description of film showing normal heart action in *THE JOURNAL* Dec. 23 1933 page 2078 Honorable Mention Scientific Exhibit A M A 1933

Grant 231 1932 George T Pack Memorial Hospital New York \$500 to complete an analysis of 300 cases of melanoma (See grant 179 1930)

Grant 238 1932 Harold E Himwich Yale University \$1000 to study the relation of the autonomic nervous system to metabolism and effect of alcohol on metabolism Himwich H E and associates Effects of Alcohol on Metabolism *Am J Physiol* 101 57 1932 Metabolism of Alcohol J A M A 100 651 1933

Grant 239 1932 Victor C Jacobsen Albany \$1000 for a study of transplantable mouse melanoma Jacobsen Victor C and Klineck, Gustavus H Jr Melanin I Its Mobilization and Excretion in Normal and in Pathologic Conditions *Arch Path* 17:141 1934 Jacobsen Victor C Melanin II A Review of Chemical Aspects of the Melanin Problem *ibid* p 391

Grant 240 1932 William D McNally Rush Medical College \$650 for a study of the effect of tobacco tar on the lungs of rats and other animals McNally W D The Tar in Cigarette Smoke and Its Possible Effects *Am J Cancer* 16 1502 1932

Grant 247 1932 Wilson D Langley University of Buffalo \$250 for work on the formation of acetone bodies in diabetic animal tissue

Grant 254 1932 J Lisle Williams McCormick Institute Chicago \$200 for work on decreased dextrose tolerance in acute infectious diseases

Grant 266 1932 Herbert S Laodes Loyola University, Chicago \$400 for study of the mechanics of residual urine

Grant 269 1932 M M Wintrobe Johns Hopkins Hospital \$250 for study of vertebrate red corpuscles Wintrobe M M Variations in the Size and Hemoglobin Content of Erythrocytes in the Blood of Various Vertebrates *Folia Haemat* 51 32 1933

Grant 276 1933 Jessie L King Goucher College Baltimore, \$75 for study of effect of cortical extract on adrenalectomized rats

Grant, 277 1933 Gustav Zechel University of Illinois College of Medicine \$260 for study of growing malignant cells by moving photomicrographs

Grant 278 1933 Carl C Speidel University of Virginia Medical School \$100 for study of the myelin nerve sheath with polarized light (See grant 303 1933)

Grant 279 1933 E C Faust Tulane University \$800 for continuation of studies on Stroggyloides stercoralis

HERMAN L KRETSCHMER, Treasurer

AUDITOR'S REPORT

To the Board of Trustees January 25, 1935
American Medical Association Chicago, Illinois

Dear Sirs

In accordance with your instructions, we have made an examination of the Balance Sheet of the American Medical Association, Chicago, Illinois, as at December 31 1934, and of the Income Account for the year 1934 In connection therewith, we examined or tested accounting records of the Association and other supporting evidence and obtained information and explanations from officers and employees of the Association, we also made a general review of the accounting methods and of the operating and income accounts for the year, but we did not make a detailed audit of the transactions We now submit our report on the examination, together with related statements as enumerated in the index appended hereto

In our opinion, based on such examination the accompanying Balance Sheet and relative Income Account fairly presents the position of the Association as at December 31, 1934 and the result of its operations for the year ended on that date, subject to the following qualifications and observations

(1) The inventories of Materials, Supplies and Work in Progress in the amount of \$65 952 62, are stated in accordance with affidavits sworn to by responsible officials of the Association and have not been confirmed by us in any way

(2) In accordance with the established practice of the Association no provision has been made for (a) accrued interest on bonds (b) membership dues unpaid (c) accrued salaries and wages (d) accrued property taxes for the year 1934, and (e) accrued legal fees

(3) Subscriptions paid in advance represent an estimated amount based on cash received for subscriptions for the year 1935 received in the month of December 1934 This conforms with the method used in prior years

(4) Advanced payments on publications represent an estimated amount of prepaid subscriptions to *Hygeia* \$111,982 62 plus \$11 895 08 received in advance for January advertising and directory sales and service.

Under date of August 15, 1934, the Association property was appraised by the American Appraisal Company. The value of the property as shown by the appraisal was considerably in excess of the book value of the property. It was decided by the Board of Trustees not to place the appraisal value on the books of account. As recommended by the appraisal company the rate of depreciation was reduced on buildings from 5% to 2½% and on machinery and equipment from 20% to 5% of the diminishing book values.

We have received a letter from Messrs Loesch, Scofield, Loesch and Burke, acting as attorney for the Association, stating that during the year ended December 31, 1934 all lawsuits pending against the Association have been definitely terminated without liability for damages against the Association. We have also received a certificate from an official of the Association stating that there are no contingent liabilities at December 31, 1934.

Fidelity insurance is carried against the undermentioned officers and employees of the Association in the amounts here stated:

Dr Olin West General Manager	\$10 000 00
Dr Herman L. Kretschmer Treasurer	10 000 00
E. C. Shelly Cashier	10 000 00
E. A. Hoffman Assistant Cashier	2 000 00
Sundry Employees (eight \$1,000 00 each)	8 000 00
Total Fidelity Insurance	<u>\$40 000 00</u>

We have pleasure in reporting that the books are well maintained and that every facility was afforded us for the proper conduct of the examination.

Yours truly, PEAT, MARWICK MITCHELL & Co

REPORT OF THE JUDICIAL COUNCIL

To the Members of the House of Delegates of the American Medical Association

The report of the Judicial Council is withheld from publication pending a meeting of the Council

REPORT OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

To the Members of the House of Delegates of the American Medical Association

I COMMISSIONS OF THE HOUSE OF DELEGATES

1 At the Milwaukee session the House of Delegates referred to the Council on Physical Therapy and the Council on Medical Education and Hospitals a resolution introduced by Dr J Gurney Taylor requesting the formulation of standards for schools of occupational therapy. All of the eleven existing schools have been visited. The Council has conferred with experienced workers in this field and now presents for approval in supplement A, the Essentials of an Acceptable School of Occupational Therapy.

2 At the Cleveland session the House of Delegates adopted a resolution introduced by Dr G Henry Mundt, to the effect that the staffs of hospitals approved for intern training should comprise only members in good standing in their local county societies. A letter has been sent to all intern hospitals advising them of this action. When the next census of hospitals is taken, the Council will be in a position to know whether further action is needed.

3 A resolution introduced by Dr D C McKenney of the Section on Gastro-Enterology and Proctology was referred to the Board of Trustees and the Council on Medical Education and Hospitals for determination of methods of examination and certification in these specialties. The Council expects to be able to develop a comprehensive plan for the identification of qualified physicians specializing in these and related fields of medicine.

4 The House of Delegates also referred to the Council a recommendation of President Lewis that assistance be given to state societies in establishing postgraduate courses of instruction. Two excellent papers on this subject were presented at the Annual Congress on Medical Education, Hospitals and Licensure in February. The Council begs leave to report progress.

5 The resolution of the Section on Radiology, introduced by Dr Albert Soiland, was also referred to the Council. On investigation and conference with certain leaders in the field of radiology, it was developed that no single method of compensating the radiologist for his service is universally applicable that without violating the Principles of Medical Ethics of the Association his remuneration may be in the form of salary, fees or commission, or any combination of these but that in no case should there accrue to the hospital a substantial profit over and above the reasonable cost of maintaining the department nor should the patient be exploited through excessive fees. While these principles have been clearly and repeatedly affirmed by the House of Delegates the application of the principles to individual cases sometimes involves complex accounting problems. It is believed that where differences of opinion arise they should be adjudicated by the local medical societies.

6 The resolution on anesthesia introduced by Dr James N Vander Veer, was also referred to the Council. At the February Congress this subject was presented by Dr F H McMechan, secretary general of the International Anesthesia Research Society and discussed by physicians, surgeons and hospital administrators as well as by the director of the Bureau of Legal Medicine of the Association. Opinions expressed were so widely divergent that the Council deems it inexpedient to take action at this time.

7 A resolution from the Section on Ophthalmology condemning the practice of medicine by optometrists was presented by Dr Emory Hill. Although not specifically referred

to the Council, steps have been taken to bring this action to the attention of hospitals on the Council's approved (registered) list.

II SURVEY OF MEDICAL SCHOOLS

8 In the fall of 1933 the Council determined that a comprehensive resurvey of medical education was needed and to this end solicited the cooperation of the Association of American Medical Colleges and the Federation of State Medical Boards of the United States. The Trustees authorized a special appropriation and Dr Herman G Weiskotten of Syracuse was added to the Council's staff. Inspections were begun in September 1934. To date forty-five medical schools have been visited, chiefly in the Eastern and Southern sections of the country. In all cases Dr Weiskotten has been accompanied by a member of the Council or a representative of one of the cooperating societies. As a result of these observations, the Council found it necessary at its February meeting to withdraw approval from the University of West Virginia School of Medicine.

The facts elicited by questionnaires and conditions reported by the inspectors will, it is believed, afford a substantial basis for a thoroughgoing revision of standards and a reappraisal of the aims and methods of medical education. Already it has been discovered that some schools are accepting poorly trained students, most of whom ultimately fail. The Council has issued a general warning against the admission of larger classes than can properly be accommodated or than can reasonably be expected to satisfy approved scholastic standards.

9 The Council, together with the College Association, the Federation of State Medical Boards of the United States and the National Board of Medical Examiners has worked out a procedure for restricting the number of poorly trained students who matriculate in the universities of Europe because they cannot gain admission to the medical schools of the United States and Canada. Unfortunately, the extramural schools of Scotland do not cooperate with us and admit each year large numbers of applicants who have already been rejected in this country.

III INSPECTIONS

10 During the past year, the Council's staff has visited 592 hospitals with reference to registration 175, with regard to approval for training interns 157, for residency approval 30, and 230 tuberculosis sanatoriums. The net gain of intern hospitals was 22 and of residency hospitals 32 and the decrease in the number of registered hospitals in 1934 was 103.

11 The survey of hospitals and sanatoriums caring for patients with tuberculosis as well as departments of general hospitals devoted to this purpose, has been completed. A report of this undertaking is in preparation and will be available, probably, in a few months.

12 In addition to schools of occupational therapy, referred to in paragraph 1, the Council has made inspections of schools for the training of physical therapy and laboratory technicians. Analysis of these reports and the formulation of standards will proceed during the coming year.

IV PUBLICATIONS

13 The Council has prepared and distributed a list of textbooks, reference works and journals suitable for a hospital library. It has also contributed substantially to five special issues of THE JOURNAL.

14 The Council desires to call particular attention to the Hospital Number, issued March 30 1935. The distribution of hospitals is graphically represented by state maps, and the significant fact that the country is already oversupplied with general hospitals is incontrovertibly shown. Furthermore, it is demonstrated that, in those sections of the country where the ratio of beds to population is low and where some are inclined to assume that additional hospitalization is needed the actual utilization of existing facilities is also low. The conclusion is inescapable that where the public demands hospital facilities they have been provided, and that in sections where the public does not avail itself of more than 50 per cent of the opportunities for hospital care that now exist it would be futile to provide more.

15 In the State Board Number of THE JOURNAL, it is shown that, during 1934, 7,730 physicians were licensed to practice medicine in the various states. Of these, 5,435 represent actual additions to the number in practice. At this rate, according to the report of the Commission on Medical Education, the ratio of physicians to population will steadily increase. This situation greatly enhances the menacing importance of the fact that a number of states continue to examine and license graduates of unrecognized schools. After a quarter of a century of effort on the part of the Association to raise the standards of medical practice there are still four states which flagrantly evade the responsibility to protect the lives of their citizens.

SUPPLEMENT A

ESSENTIALS OF AN ACCEPTABLE SCHOOL OF OCCUPATIONAL THERAPY

I ORGANIZATION

1 A school of occupational therapy should be incorporated under the laws regulating associations which are operated not for profit. The control should be vested in a board of trustees rather than an individual. This board should be composed of public spirited men or women receiving no financial benefits from the operations of the schools. The trustees should serve for fairly long and overlapping terms. If the choice of trustees is vested in any other body than the board itself this fact should be clearly stated. Officers and faculty of the school should be appointed by the board.

2 Affiliation with a college university or medical school is highly desirable but is not an absolute requirement.

3 Schools of occupational therapy should not be operated by hospitals independently. It is understood however, that hospitals are needed for practice training and especially for graduate training in the special branches of occupational therapy.

II FACULTY

1 The school should have a competent teaching staff graded and organized by departments. Appointments should be based on thorough education and training and successful teaching experience. Nominations for faculty positions should be made in accordance with academic custom. The staff should include not less than one regular salaried instructor and one registered occupational therapist. The question of full time and part time appointments is not as important as the qualifications of the instructors who should be specialists or exceptionally well trained and well qualified in the lines they are teaching.

III PLANT

1 The school should own or enjoy the use of buildings sufficient in size to provide adequate lecture rooms, class laboratories and administration offices. Equipment should be adequate for teaching and training. Anatomic charts, manikins and dummies should also be provided. There should be a library receiving regularly all the leading periodicals pertaining to occupational therapy, current numbers of which should be easily accessible to the students.

IV ADMINISTRATION

1 *Supervision*—There should be careful and intelligent supervision of the entire school by the dean director or other executive officer who by training and experience, is fitted to interpret the prevailing standards and who is clothed with sufficient authority to carry them into effect.

2 *Records*—There should be a good system of records showing conveniently and in detail the credentials, attendance, grades and accounts of the students, by means of which an exact knowledge can be obtained regarding each student's work. Schools should require that students be in actual attendance within the first week of each annual session and thereafter. Except for good cause no credit should be given for any course when attendance has been less than 80 per cent.

3 *Credentials*—The admission of students to the occupational therapy school must be in the hands of a responsible committee or examiner, whose records shall always be open for inspection. Documentary evidence of the student's preliminary education should be obtained and kept on file. When the occupational therapy school is an integral part of the university, this work usually devolves on the examiner or registrar.

4 *Advanced Standing*—At the discretion of the administration advanced standing may be granted for work required in the occupational therapy curriculum which has been done in other accredited institutions. Official verification of previous work should be obtained by direct correspondence. Preliminary qualifications should also be verified and recorded.

5 *Number of Students*—The number of students admitted to the training course should not be excessive. In practical work of a laboratory nature the number of students that can be adequately supervised by a single instructor is, in general experience about fifteen. In lectures the number may be much larger. A close personal contact between students and members of the teaching staff is essential.

6 *Discipline*—All training schools reserve the right to drop a student at any time for any cause which the school authorities deem sufficient.

7 *Publications*—The school should issue at least biennially, a bulletin setting forth the character of the work which it offers. Such an announcement should contain a list of the members of the faculty with their respective qualifications.

V PREREQUISITES FOR ADMISSION

Requirements for admission shall be

1 *Age*—The admission of candidates should be governed by the fact that it is required that each student be not less than 21 years old at graduation.

2 *Education*—All candidates must furnish proof of having completed a high school education or its equivalent. In addition it is desirable that all candidates, except those for the degree course, shall have had at least one year, and preferably two years, of further education or successful experience in college, art school, social service, nurses' training or the commercial field.

Candidates for admission to a training course in a college or university which is combined with work leading to a bachelor's degree should be required to comply with the regular entrance requirements of the institution concerned.

3 *Character*—All candidates should be required to present evidence of good character and general fitness, the evidence of which should be investigated and duly weighed by the school concerned.

4 *Health*—All students should be given a physical examination under the supervision of the school as soon as practicable after admission and this examination should be repeated annually. The first examination, at least, should include a roentgen examination of the chest.

VI CURRICULUM

1 *Length of Course*—The minimum length of the course should be twenty-five calendar months (100 weeks) of full time training. The course should include not less than sixteen months (sixty-four weeks) of theoretical and technical work, and not less than nine months (thirty-six weeks) hospital practice training under competent supervision all as set forth in detail in succeeding sections.

2 *Distribution of Time*—The two years devoted to theoretical training should include not less than sixty semester hours of which not less than thirty semester hours should consist of

systematic instruction and not less than twenty five hours of laboratory procedures. In special cases a variation of 10 per cent is permissible.

3 The hours devoted to theoretical training should be still further subdivided as follows

(a) Biologic Sciences include	
Anatomy	15 Semester Hours
Physiology	
Neurology	
Kinesiology	
Psychology	
Psychiatry	
(b) Social Sciences	4
(c) Theory of Occupational Therapy	4
(d) Clinical Subjects include	
Orthopedics	4
Tuberculosis	
Cardiac Diseases	
Blindness and Deafness	
Contagious Diseases (including Bacteriology if this subject is not given elsewhere)	
General Medical and Surgical Conditions	
(e) Electives	3
Total	30

4 Practical work in the various occupations should be allotted not less than twenty-five semester hours. The following subjects should be covered

Design	Leather
Textiles	Plastic Arts
Wood	Recreation
Metal	Miscellaneous

5 The curriculum outlined above should be in effect not later than Jan. 1, 1939

REPORT OF THE COUNCIL ON SCIENTIFIC ASSEMBLY

To the Members of the House of Delegates of the American Medical Association

At this annual session the two greatest organizations of physicians on the American continent are brought together for participation in a joint program intended to advance the cause of scientific medicine to promote the public health and to cement good will and fellowship further between the physicians of two great nations. We of the American Medical Association are honored by the presence of many members of the Canadian Medical Association and are grateful for the contributions that will be made to the scientific programs by a number of distinguished physicians from our neighbor country.

The Council on Scientific Assembly has had its usual meetings during the past year and has given official attention to all matters that have been brought before it.

The regular annual conference of section secretaries with the Council on Scientific Assembly was held in Chicago Nov. 10, 1934. The President-Elect, the Secretary, the Chairman of the Council and the Chairman of the Central Program Committee of the Canadian Medical Association were invited to attend this conference and were present. These distinguished gentlemen rendered valuable aid in connection with the preparation of the official program for the Atlantic City session.

The usual arrangements for the meetings of the sections of the Scientific Assembly have been made. Sessions on Anesthesia, Military Medicine and the History of Medicine will be held in the Section on Miscellaneous Topics.

An excellent program has been prepared for the General Scientific Meetings to be held on Monday and Tuesday, June 10 and 11.

No resolutions or memorials have been submitted to the Council during the year.

CALIFORNIA AND SICKNESS INSURANCE

A REPORT BY MORRIS FISHBEIN, M.D.

Editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

Since the House of Delegates of the California Medical Association went on record as favoring compulsory sickness insurance, some progress has occurred in that state in making the action effective. On April 12, 1935, the California legislature published as a part of the *Senate Daily Journal* the report of the Senate Committee on the "Investigation of the High Cost of Sickness." There are various points of view as to how this senate committee happened to be appointed and particularly with the extraordinary title emphasizing medical costs under which it makes its report. Rumor has it that Dr. Walter B. Coffey, chief surgeon of the Southern Pacific Railroad, was primarily responsible—and he confirmed this impression in his statement to the legislature. The preliminary statements of the report indicate that certain foundations were expected to assist largely in making the surveys. This authorization of the California Senate was plainly predicated on the belief that certain foundations, philanthropists and others interested would welcome the opportunity to make ample contributions to carry on this work. This assumption was warranted because certain well-financed foundations had expressed such active interest in the subject and were spending much money to ascertain what could be done in a legislative way. It is significant that the results of the survey duplicate the results of similar surveys made by these foundations in other places. Yet financial assistance was not given by them.

The committee was empowered by the resolution to choose its own officers and drafted Dr. Celestine J. Sullivan as its coordinator-secretary. The record of Mr. Sullivan for he is that kind of doctor, is well known to physicians who have followed the course of medical affairs in California. Some years ago he pleaded with California doctors to take up advertising. The answer to this survey, as the answer to most of the others that have been conducted under similar auspices in this country, is that the surveys found out exactly what they were predestined to find out with the setups that they had.

The report of the Senate Committee on the "Investigation of the High Cost of Sickness" opens with a general statement by the senate committee on the nature of scientific advancement and then emphasizes the importance of the insurance method as a means of meeting the costs. Thus, it says: "Health service insurance will prevent such economic and social disaster, and a vast amount of unnecessary sickness and thousands of unnecessary deaths." The California survey contacted 20,560 families, 1,112 physicians, 646 osteopaths, 828 dentists, 192 hospitals and 96 clinics. It is pointed out that California has a higher proportion of doctors to the population than any other state and that hospital facilities are unevenly distributed. During 1935, state institutions operated at a 90 per cent capacity while private institutions operated at approximately 53 per cent. Hospitals throughout California are suffering with the poor financial conditions and a considerable amount of legislation has been introduced into the California legislature that would save the hospitals but if enacted, would also put the hospitals in the practice of medicine.

The California medical economic survey indicated that in 1933 one third of the doctors were making net professional incomes of less than \$2,000, one half less than \$3,000 and three fourths less than \$5,000. It must be pointed out, however, that the questionnaire method was used in this survey and that only 1,112 doctors out of the total profession of 10,490 in California replied. It may be assumed that the doctors in the higher income levels did not reply. One half of the osteopaths who replied earned less than \$2,000 and five sixths earned less than \$4,000. Of the 18,863 families studied, 15 per cent had in 1933 incomes of less than \$500, 39 per cent less than \$1,000 and 51 per cent less than \$1,200. Thus more than one half of the people of California according to the report receive less than a living income. Only 4 per cent of the families concerned reported incomes of more than \$5,000. The figures also seem to indicate that the families in the lower income brackets

required more medical care than the families in the higher income brackets. The survey also reported that the lower income classes did not get the care they needed, as based on their own replies to the questionnaires. The survey concludes with the suggestion that families with incomes of \$1,200 or less cannot afford unexpected medical and dental charges between \$100 to \$500 during the year, yet 12 per cent of the families studied reported such charges. The report indicates that the investigators believe their survey is representative of conditions throughout California.

The report also discusses the distribution of medical, eye and dental care for families on relief, and indicates that physicians bear the heaviest burden for the sick, giving freely of their services to those unable to pay and lowering their fees for those able to pay only partially. The physicians bear 70 per cent of the total amount due for services to families under \$3,000 annual income and approximately one half of the amount owed by the highest income group.

The survey cost about \$100,000 and duplicates the results of the Michigan and other surveys made by similar surveys.

Continuing the discussion it is pointed out by the senate committee that the action of California is likely to be looked on as a model for American legislation in this field and it asks for a definite separation of cash benefits from health service insurance. The California law proposed is based on foreign experience. The senate committee then presents certain amendments offered to proposed legislation in this field which will be analyzed in THE JOURNAL.

To this report there are a considerable number of appendices. The first is an address given by Senator F. H. Tickle in March 1934 at a University of California conference on government, at which Dr. Ray Lyman Wilbur presided. In this address Senator Tickle presented a definite bias in favor of a sickness insurance system. He listed foreign groups that have already adopted such methods and he emphasized the right of the California legislature to pass such legislation.

The second appendix is a statement of Senator Tickle at the public hearings held by the Committee in December 1934. In this statement Senator Tickle supported the majority report of the Committee on the Costs of Medical Care. He attacked the minority report and particularly Dr. Olin West and the American Medical Association giving the impression that Dr. Olin West wrote and was responsible for this report—an impression absolutely unwarranted and untrue. He charged that the British health insurance system had been misrepresented in this country by American Medical Association propaganda but indicated that California did not recommend the panel system.

The statement of Senator Tickle was supplemented by a statement from Chester H. Rowell, who was introduced by Celestine J. Sullivan as chairman of the Social Health Insurance Commission of 1917-1918. At that time Mr. Sullivan was opposed to sickness insurance but he has since apparently had a change of heart. Mr. Rowell modestly concludes his statements by stating that the medical 'men in California' probably know more about it than any number of men anywhere else in the United States.

The next speaker was Dr. French of the Western Hospital Association, who supported the plan of sickness insurance for the low income groups, and then Frank McDonald, industrial accident commissioner, who is also president of the State Building Trades Council of California, indicated that the building trades would support legislation for compulsory health insurance in California. The next speaker was Dr. Walter B. Coffey, who indicated that he had formerly opposed compulsory sickness insurance but that he was very much in favor of a system that would provide adequate care at a reasonably monthly rate. He described the sickness payment system used by employees of the Southern Pacific Railroad and the Southern Pacific Hospital Association. His statement was supported by the head of the railway engineers of the Pacific Coast.

The next statement was by Dr. T. Henshaw Kelly, chairman of the Council of the California Medical Association. Dr. Kelly indicated that an attempt was being made to crystallize the opinion of the California medical profession and introduced Dr. Harry H. Wilson, secretary of the Survey Committee of

the association. Dr. Wilson described the scope of the survey as of that date.

Dr. Roy Green, representing the dental profession, asked some delay pending action by the federal government. Celestine J. Sullivan indicated that any federal plan would involve coercion of the various states and that the federal government can enact only certain laws for the District of Columbia.

A statement was also received from the California Osteopathic Association unanimously approving the insurance plan as outlined by Senator Tickle and Mr. Rowell.

The next speaker, Rodney Yoell, urged the establishment of compulsory sickness insurance in California and recommended that organized medicine sit with the senate committee to work out a proper solution. Dr. Yoell concluded:

Now I believe also that medicine organized medicine will sit down with you and work out a happy solution to this problem because I know in times past that no call has ever been made by an existing civilization on the medical profession wherein the medical profession has been derelict in its duty and it has been unhearing and unmindful of that call. You must be a little patient with us within the next few weeks, in our deliberations and with our contentions but I do believe this. That just as you gentlemen of this senate committee, and you men and women representing the various hospital associations—the great Catholic sister hospitals, the non-Catholic hospitals, the great universities, the labor organizations, the industries—are sitting in this room now and giving an honest intent and a keen mind and an absolutely penetrating judgment on this existing problem and its solution—so too will the medical profession come forward and join you in this study.

We of California who were born on this soil and those who live from the bounty of this soil love this state, we love this our California and we feel absolutely that in your hands and in the hands of the fellow citizens of this state a solution to this problem will be worked out which will provide for every solvent person competent adequate medical care that will retain to the medical profession the right to the competitive effort of practice and that marching forward shoulder to shoulder a great load of preventable want and misery will be lifted from the shoulders of the people of California.

Representatives of various railroad employee associations in connection with the Southern Pacific Railroad also spoke in favor of the legislation.

Dr. Morton Gibbons, representing Stanford University, said that most physicians felt that health insurance is inevitable. He said that the medical profession would not oppose a health insurance law or compulsory health insurance but that they want to be sure that the law will give proper consideration to medicine.

Senator Tickle said that the Canadian report pointed out that there had been a 39 per cent decrease in sickness in England since they had their system of sickness insurance in effect. (This statement is so preposterous that it is comical. The figures actually show more visits to doctors and the sickness rates and death rates of the United States are better than those of other civilized countries of approximately the same populations.—Ed.)

Celestine J. Sullivan pointed out that the University of California provides medical service to 9,800 students in residence at an annual cost of \$17.86 per student. Professor May, economist of the University of California, brought up the data published by the Milbank Memorial Fund indicating the fear of the medical profession in relationship to sickness insurance. He pointed out that, while he was a member of the advisory council of the California Medical Economic Survey, his opinion had not been asked in drawing conclusions. Dr. Harry Wilson said that the opinions had been received and that they would be given consideration. Professor May said that he would like to have the faculty of the University of California receive the same services as were given to the students. He also indicated the desirability, as pointed out by Mr. Kingsbury of the Milbank Fund, that the state participate in the payment for sickness insurance.

Dr. John Graves said that there are innumerable California families and California citizens who cannot secure adequate medical care without going to the verge of pauperization and that the needs must be met.

Mr. Von Ellsworth, representing the California Farm Bureau Federation, felt that because of the transient population of California there should be a larger taxing unit than the county unit to provide for the medical needs of the indigents.

Dr. Jacob C. Geiger, health officer of San Francisco and president of the San Francisco County Medical Society, felt that there must be unanimity and loyalty among the medical

profession He urged that the San Francisco County Medical Society cooperate with the state medical association and pointed out that the European experiences could not be applied to this country Dr Geiger did not believe that the doctors should be paid for caring for the indigent sick when they were used for teaching purposes by the universities

Dr Harry Wilson pointed out that the California Medical Association did not approve the Public Health League for fear that it would misrepresent medicine to the community

Dr Sloman representing the dental association, pointed out that they had not adopted any definite views in relationship to compulsory sickness insurance and that no system of sickness insurance of which he had knowledge provides adequate service for dentistry He did, however hope that some system might be worked out in California that would be satisfactory

Dr Philip King Brown condemned the individuality of the medical profession He attacked the Public Health League as fighting health insurance and expressed his belief that the compulsory sickness insurance would not lower the standards of medical care if it was run by medical men He also expressed his disapproval of the Alameda County plan and the San Fernando plan and said that the statements of Frederick L Hoffman on sickness insurance were outside the facts

Dr Alson R Kilgore expressed his belief that some form of distribution of medical care would have to be developed, and he was led by Celestine J Sullivan into an expression of approval for health insurance Mr E R Zion spoke in behalf of groups that want to get their own group insurance and hoped that some proper system would be developed for such groups

Dr Loos of the Ross-Loos clinic described the service of his group and asked what would be done in the matter of payment of physicians under the proposed compulsory sickness insurance bill

Dr Coffey indicated that he was one of the originators of the resolution introduced into the senate two years ago providing for the present investigation and providing for a compulsory sickness insurance system

The next appendix indicates the authority given to Celestine J Sullivan by the senate committee and the resolutions adopted by the California Medical Association in relationship to compulsory sickness insurance The California Medical Association's resolutions demanded that

1 The patient shall have absolutely free choice of physician and hospital

2 The medical profession shall determine the scope the extent standards quality compensation paid for and all other matters and things related to the medical and medical auxiliary services rendered under this system

3 There shall be no provision for cash benefit

4 The patient shall receive adequate treatment and the physician shall receive adequate compensation

5 The foregoing principles shall be maintained with such modification thereof as may from time to time be recommended or approved by the profession he it further

Resolved That the California Medical Association offer its full aid and cooperation to the interim committee of the senate and of the state of California charged with the study of this problem to the end and that any measure which shall be passed establishing a health insurance system at the 1935 session of the California legislature shall contain the above principles and be it further

Resolved That there be formed a special committee authorized and empowered to act herein constituted as follows The legislative committee of the association and three members of the association to be appointed by the speaker of the house of delegates

This is the resolution which commits the state medical association to work with the interim committee in developing a sickness insurance law Similar resolutions were adopted by the California Dental Association

The next appendixes provide tables and statistical data of the California Medical-Economic Survey and another appendix gives the compulsory national plans adopted in various foreign countries

A special appendix, marked 'Appendix G,' is devoted to the American Medical Association This bears the delicate touch of the literary style of Celestine J Sullivan and was apparently written within the last two weeks It describes the action taken

by the special session of the House of Delegates of the American Medical Association, February 15 and 16 The statement says

The law of the Medes and the Persians which altereth not was followed by the A M A House of Delegates at Chicago in reiterating its opposition to all forms of compulsory sickness insurance' The A M A delegates in Chicago reacted like the travelers described by Newman Nothing which meets them carries them forward or backward to any idea beyond themselves

One of the returning delegates expressed the opinion that those distinguished doctors were men of personal charm good golfers and scientifically and financially self assured [This will be news to the House of Delegates—En] It is not surprising that those delegates with lucrative practices among citizens with ample incomes fail to grasp the pressing problem of the lower income groups They are not socially conscious of the grievous evils of the present system which are revealed by tables contained in the report of this senate committee. They would not of course prolong the agony caused by the present system if they understood the problem If they understood the problem they would follow the leadership of the House of Delegates of the California Medical Association who have looked ahead with clear vision and seeing that the present system must be changed to meet the demands of today recommended compulsory health insurance so that citizens within the lower income brackets may be assured adequate care at prices they can easily afford

Then the resolution commends the California Medical Association for its action and attacks the American Medical Association for attempting to usurp the rights of the state. It also points out that the American Medical Association in 1930 adopted a resolution "that each state should be left free to formulate its own health program There follows further attack on the actions of the House of Delegates of the American Medical Association Then appears the statement

Testimony given by California physicians at the public hearing of the senate committee in San Francisco showed the extensive propaganda against health insurance conducted by the A M A in this state We are informed by members of the California Medical Association that Dr Morris Fishbein's address on health insurance before the Dental Association in Oakland did not have any official sanction of the medical profession [This is untrue!—Ed] In fact Dr Fishbein although editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION failed to get an invitation to address any of the constituent county societies of the California Medical Association [This is also untrue!—Ed] Dr Fishbein is an entertaining talker [This is true!—En] and California welcomes every visitor The California Medical Association after due deliberation having gone on record for compulsory health insurance very consistently refused to permit Dr Fishbein to confuse the issue by inciting prejudice and opposition Dr Fishbein's anti health insurance addresses in California would not merit our attention if they were not designed to undermine the constructive action of the California Medical Association The A M A was powerful enough to make the American College of Surgeons recede from its position on health insurance it was potent enough to make the Michigan State Medical Society lay down and turn face downward its expensive survey and report on health insurance but the A M A was impotent to delay or dismay the California Medical Association by ukase [The statements relative to the American College of Surgeons and the Michigan State Medical Society are untrue!—Fn] The narrow viewpoint of the official A M A on the shores of Lake Michigan compare in breadth and depth with the broader vision of the C M A on the shores of the Pacific as the lake compares to the ocean

There seems to be something about Chicago Ill, that adversely affects the minds of medical men This is not the first time that Chicago doctors indicated that they are not constructively interested in the problem of reduction of the high costs of illness

There follows a report by California newspapers of an interview given by Dr Louis Schmidt in Chicago and four or more pages about Louis Schmidt taken from Chicago newspapers This of course, does nothing but cloud the issue

The final appendix gives the address by Dr Morris Fishbein before the meeting of the American Academy of Political and Social Science in Philadelphia Feb 7, 1934, and the address by William Trufant Foster on the same occasion The document then concludes with some cartoons, favorable to sickness insurance from California newspapers, and contains a list of publications consulted by the senate committee in developing its opinions It is significant that very few of the publications of the American Medical Association seem to have been brought to the committee's attention

Peas, Peanuts and Beans—The meat substitutes of vegetable origin are chiefly those seeds known as legumes of which peas, peanuts and navy kidney lima and pinto beans are the most commonly used varieties—Newburgh L H, and Macmillan Frances The Practice of Dietetics, New York Macmillan Company 1934

REPORTS OF AMERICAN MEDICAL ASSOCIATION OFFICERS

In this issue of *THE JOURNAL* appear the reports of the various officers, bureaus and committees of the American Medical Association which by action of the House of Delegates are published one month in advance of the annual session in order that the members of the Association and the delegates may be informed concerning the activities of the Association during the year. Attention is called particularly to the statement of policy adopted by the House of Delegates at the special session in February which constitutes today the policy of the American Medical Association on the subject of sickness insurance and economic security. This report appears on page 1608.

It will be seen from the Treasurer's and Auditor's reports that the finances of the Association are in excellent condition and that the number of members and of Fellows has increased over the number enrolled in the preceding year. Thus far the Association has weathered satisfactorily the financial depression. Because of the nature of the times, the Bureau of Economics has been under constant strain during the past year carrying out investigations of economic problems and advising physicians throughout the country concerning special problems in various states.

Especial interest attaches also to the report of the Bureau of Legal Medicine and Legislation, which begins on page 1616. Here physicians will find up-to-the-minute accounts of the present status of important legislation in various states and also of legislation now before Congress. Here also is the information relative to Emergency Relief, the present status of food drug and cosmetic legislation and many similar matters.

Every physician will find this report of the greatest importance in relation to his daily work. All the other councils and bureaus of the Association have been exceedingly active in providing for the needs of the medical profession and in carrying out the policies adopted by the House of Delegates encouraging scientific advancement and aiding medical research.

EXPLAINING CALIFORNIA

Under the heading Medical Economics in this issue of *THE JOURNAL* appears a transcript of hearings and various official actions of the legislature and medical bodies in California in relationship to sickness insurance. Politically the situation in California is exceedingly complicated. The medical profession seems to be playing the role it thinks best under the circumstances and the conditions. Nevertheless the assumption of this role has brought about some peculiar situations. For example the California Dental Association invited the Editor of *THE JOURNAL* two years ago and again in May 1934 to address the annual session of that body. The California Medical Association at that time gave its approval to the visit. Because of the developments in the political situation, state medical officers of California apparently thought it wise more recently that the point of view of the American Medical Association be prevented as far as possible from reaching the membership of the California Medical Association. Notwithstanding the apparent desire of some state officers to avoid presentation of the point of view of the American Medical Association, the medical society in Fresno invited the Editor to address a joint meeting of doctors and dentists in that community. Addresses were made also before three public forums, and several meetings of physicians and dentists. The point of view of the American Medical Association was circulated widely in the press through interviews and reports of addresses. As will be seen from a reading of the outline which appears under the department of Medical Economics, certain lay political leaders in California rejoiced—without warrant—at the suppression of the American Medical Association point of view.

Apparently the officers of the state medical society feel that compulsory health insurance is sure to come in California and that their only hope of obtaining some recognition for the medical point of view is to cooperate fully with the interim committee appointed by the senate of California in response to a resolution recommended by Dr. Walter B. Coffey two years ago. As was explained in an editorial in *THE JOURNAL*, April 6, page 1243, a number of bills are before the California legislature, including six or seven bills for compulsory sickness insurance, one bill opening all the hospitals of the state to all the people regardless of ability to pay, and another licensing corporations to practice medicine in California. Moreover, the state is overrun with cultists of various types and with all sorts of corporation practice, group practice, club practice, industrial practice and similar schemes. The survey made jointly by the California State Medical Association and the interim committee of the senate, like most such surveys, hardly seems to have scratched the real surface of medical conditions, yet the results of the survey are cited in support of the action to which the various bodies concerned in the legislation seem to have been rather largely committed before the survey was

undertaken. It is clear that the Milbank Fund and other foundations have been active in propaganda in California.

As the onlooker from without the Editor would venture the prediction that all will not be as rosy in California as it may now seem to the bespectacled, rose-colored vision of some of the proponents representing the California Medical Association. It should be obvious from the statements that have been made and the hearings that have been held that the very factors in medical care which the profession will demand will not be favorably received by the political group, who will eventually dominate the sickness insurance system in California. The dental profession, some assert, has received inadequate consideration in the proposed legislation and will perhaps oppose the bill that has been offered. The medical profession will perhaps find itself ultimately in a situation in which it will have to oppose the legislation for which it is now responsible, mainly because it decided to compromise rather than to fight to the finish on the principle and the issue.

A complete study of all that has occurred in California indicates to any one who has some understanding of our American political system the difficult path which the leaders of California medicine are treading. Perhaps they will find their way successfully out of the morass without engulfing their profession in a system which will lead to a lowering of the standards of medicine and the quality of medical care in that state.

THEORIES ON THE GENESIS OF GASTRODUODENAL ULCER

The circulatory theory of the genesis of gastric ulcer advanced by Virchow and Hauser in 1853 suggested that such ulcers are produced by an infarction of a terminal blood vessel with consequent necrosis, the starting point for the digestive action of the gastric juice. In this theory the role of the excessive gastric secretion assumed especial importance and was considered the decisive factor by Riegel Boas, Sippy, von Bergmann and, in fact the majority of clinicians.

Chronic ulcers, it was pointed out, occur only in that portion of the gastro-intestinal tract which is exposed to the action of the hydrochloric acid, viz. the stomach and the first two inches of the duodenum. They are rare in the cardia. When the jejunum is exposed to the action of gastric juice following a gastro-enterostomy for ulcer, marginal peptic ulcer develops not infrequently. However, such ulcer has never been observed when the gastro-enterostomy is performed for gastric cancer. Of particular interest are the peptic ulcers of Meckel's diverticulum in which histologic studies revealed the presence of islands of gastric mucosa in the diverticulum. The ulcer itself is analogous to the marginal peptic ulcer. Ulceration here is ascribed to the peptic effect of the gastric juice on the adjacent intestinal mucosa.

The wave of enthusiasm for stomach resections which began about twenty years ago and was advanced with particular fervor in Germany, supplied abundant material for histologic studies and a new point of view. In all cases of gastric or duodenal ulcer, gastritis or duodenitis appeared. The inflammatory areas frequently contained multiple small oval round and linear erosions, the largest of which could be recognized macroscopically as superficial erosions. The fact that he failed to find any change in the blood vessels in these areas was stressed by Konjetzny,¹ who did not observe any evidence of hemorrhage, anemic necrosis or hemorrhagic infarction. Inflammatory changes in the mucosa without any evidence of peptic digestion were, however, observed with great regularity. Konjetzny, Puhl, Moscovitz, Kalina and others, supported by histologic studies, established that ulcerative gastritis or duodenitis is the important factor in the pathogenesis of the ulcer disease. Inflammatory gastritis and duodenitis were the precursors as well as the accompanying anatomic factors and explained the chronic course of the disease with its remissions and exacerbations. These observers denied the importance of pepsin hydrochloric acid in the conversion of an erosion into an ulcer. The neurogenic-spasmogenic theory of von Bergmann² was based on the clinical observation that many of the patients with ulcer exhibited disturbances of the vegetative nervous system. Eppinger and Hess suggested that vagotonia provoked spasms of the muscularis and of the muscularis mucosae, leading to areas of ischemia, which favored the formation of erosions and ulcers. A spastic condition of neurogenic origin operating on the vessels and the muscular apparatus was the causative factor. But experiments on severing the vagi and on extirpating the sympathetic and the celiac plexus gave contradictory results, and the hypothesis that all bearers of ulcer are vagotonic or sympathetotonic did not find acceptance.

The mechanical-functional theory advanced by the Aschoff school was based on the existence of a special anatomic unit. The gastric channel of Waldeyer, "the magenstrasse," occupying the lesser curvature, is the seat of 90 per cent of all gastric ulcers. The contention that food and gastric juices move along this path to reach the pylorus, thus exposing it to greater mechanical and chemical injury than the rest of the gastric mucosa, is not supported by the more recent roentgenologic studies. The accumulated clinical and experimental observations force the clinician and the experimental worker once more to look to the digestive power of the gastric secretion as the most important factor in the genesis of the ulcer. The next step was an attempt to produce ulcers in normal gastric mucosa by increasing the amount of the secretion as well as its

¹ Konjetzny, G. F. Entzündliche Genese des Magendivertikulalgieschwurs. Arch. f. Verdauungskr. 36: 189 (Dec.) 1924.
² von Bergmann, G. Berl. klin. Wchn. chr. 55: 524 1918.

digestive power Burkle-de la Camp³ was able to produce ulcers in rats by subjecting them to starvation and to hypodermic injections of histamine in doses sufficient to stimulate the secretion of the gastric juice but not sufficient to cause spasmodic contractions of the gastric vessels or the musculature. The ulcers thus produced exhibited a tendency to invasion, bleeding and perforation. These effects could be produced only in fasting stomachs, but fasting alone without injections of histamine failed to produce ulceration of the gastric mucosa. Sectioning of both vagi did not cause ulcer formation unless combined with histamine injections. The role of the gastric secretion in the genesis of ulcer was demonstrated even more strikingly in Silbermann's⁴ experiments. Silbermann established esophageal fistulas in dogs and subjected them to sham feedings, thus stimulating the psychic phase of the gastric secretion. The stomach continued to secrete after each feeding a secretion of acid concentration and digestive power five times as great as that of the normal secretion. When examined from fourteen to forty-nine days later, all the dogs showed ulcerations in varying stages of development. Silbermann's experiments demonstrated that excessive gastric secretion of high digestive power is capable of producing severe gastric lesions and fibrinoid necrosis and that the experimental ulcers are localized almost exclusively in the pyloric region.

Current Comment

FEDERAL PLANS FOR SOCIAL SECURITY

As our readers no doubt realize, the social security bill has passed the House of Representatives by a tremendous vote and is now under consideration by a committee of the United States Senate. Washington observers predict that its consideration may be somewhat delayed because of other important legislation which has priority. In the final bill the social service board is removed from the supervision of the Department of Labor and placed directly under the President. However, the infant and maternal welfare plans and the care of the handicapped are left to the individual states, subject however to approval of such plans by the Children's Bureau in the Department of Labor. There is, moreover, a considerable contribution for public health work to be conducted under the United States Public Health Service. The words "health insurance" and "sickness insurance" do not appear in the bill. It is interesting in this connection to read the words of Raymond Moley in his periodical *Today*, principally because Mr. Moley, it is understood, represents largely the administration's point of view.

Health insurance is not included. A violent controversy on this subject is raging in the medical profession, and the government is wisely refraining from action until public sentiment, in one way or another, shall have crystallized. In any event, provision for old age and unemployment benefits are the major parts of a program and can immediately be put into effect.

This statement by Mr. Moley is, of course, subject to the criticism that a "violent controversy on this subject" is not raging in the medical profession. The opinion of the organized medical profession, as expressed by the membership of the American Medical Association through the House of Delegates, was unanimously opposed to compulsory sickness insurance on either a federal or a state basis. If, however, the President and Congress are waiting for public sentiment to crystallize, the medical profession must realize that the forces of propaganda in behalf of sickness insurance are multiple and wealthy and that the medical profession must take far more interest in this matter and extend itself to the utmost if its views are to be brought satisfactorily before the American people.

LOS ANGELES COUNTY MEDICAL SOCIETY BUILDING

Amidst the political turmoil assailing California, as indicated elsewhere in this issue, the medical profession in Los Angeles has been benefiting to a considerable extent through the development of new headquarters for its county medical society. Apparently the wisdom and foresight of Dr. Harland Shoemaker and others in official positions many years ago developed the necessary site and the funds for the conduct of this fine venture. The new building contains an assembly hall seating from 600 to 800 people, a lunch room, recreation rooms, a library of some 30,000 volumes with subscriptions to several hundred leading medical periodicals and adequate provision for extension of the stacks devoted to periodicals, and rooms for literary medical research. The arrangements are among the finest available to a county medical society anywhere in the United States. They constitute a model for similar organizations elsewhere as to both the quality of the accommodations and the financial provisions for the future maintenance of the building and equipment.

"PRIVATE WORLDS"

Currently in the motion picture houses there is being projected a film called "Private Worlds," based on a novel of the same name by Phyllis Bottome, a well known English writer, who we understand herself spent several years in such an institution as a nurse. In developing this film, we are informed, the Walter Wanger Studios employed a competent psychiatrist full time. As a result of his advice, no doubt, the film meets medical criteria particularly as relates to the portrayal of insanity. The chief value of the film is in its emphasis to the public of the change that has taken place in psychiatry with the introduction of understanding and mildness in place of the penal methods and brutality of a previous century. Significant indeed is the portrait of Pinel, which hangs over the desk of one of the physicians who plays a leading part in this picture. Such a film is bound to be helpful to the cause of modern psychiatry by giving the public a true insight into this work. If there is any adverse criticism to be made it is over the rather sudden projection of the ordinary layman into an atmosphere of insanity without more preparation of his mind for

³ Burkle-de la Camp H. Deutsche Zeitschr. f. Chir. 220: 31 (Sept.) 1929.
⁴ Silbermann I. S. Zentralbl. f. Chir. 54: 2385 (Sept. 17) 1927.

what he will see. The scenes showing occupational therapy and doctor-patient contacts are most effective, indeed so much so that one regrets their brevity. The only inconsistency that was apparent to several medical observers was the emergency surgery performed by a psychiatrist—a rather theatrical performance, which might have been much more conceivable in an English nursing home than in an American institution of this type. One rejoices particularly that the studio which produced this film avoided the usual unfortunate spectacle of a Napoleon wandering about in search of an empire or other methods of introducing cheap comedy through the portrayal of unfortunate mental patients. A fine restraint was exercised in this regard and the producer deserves special commendation for such recognition of artistic values. Physicians everywhere will find this film interesting and, because of the facts that have been presented, a real advance in the portrayal of medicine on the motion picture screen.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

Osteopathy and Licensure

DR. FREDERICK ETHERINGTON, Kingston Ont. This article appeared in full in THE JOURNAL, April 27, page 1549

DISCUSSION

DR. WILLIAM D CUTTER, Chicago. There are two important factors which cannot always be determined from a perusal of the written announcements of such educational institutions, which are oftentimes submitted to legislative committees in support of claims as to the character of the training that is conducted. The first of these criteria is the character and the educational fitness of the students to undertake the work. The question of the training of students must be looked into most carefully, credentials must be scrutinized their source must be known, their accuracy must be guaranteed, and their terms must be carefully evaluated by one who has had long experience in dealing with documents of this sort. And unless one can determine in the first instance that the students in any school have been adequately prepared to enter on that course of instruction it is unsafe to assume that anything is accomplished by the training even though on paper it may appear that the subjects covered and the time devoted to them are quite equal to those in other institutions. The second point to emphasize is the qualifications of the faculty. The mere fact that a man is in the catalogue as a professor of anatomy is no guaranty that he knows anything about anatomy. The same thing would be true of course in other lines. Consequently, one cannot assume from simply reading in a catalogue that certain courses are given or that the character of those courses is the same as would be required in recognized institutions in the same line of teaching.

CHARLES HAZARD D O, New York. I am a member of the State Board of Medical Examiners of the State of New York, and I am an osteopathic physician. Dr Etherington said that there should be a common standard and there should. If it had existed there would be fewer independent boards in this country than there are today.

P R RUSSELL, D O, Fort Worth, Texas. I do not think this is a fair report. I do not desire to bother this organization with a long discussion of this report, which I have spent nights studying, but in fairness to the sixteen or eighteen osteopathic members of this federation I have prepared a brief on my observations of Dr Etherington's report, and I should like to request the privilege of this organization to file the same with the secretary, that is, my discussion of that report.

DR. FRANK M FULLER, Keokuk, Iowa. If practitioners of regular medicine can find their brothers of the osteopathic faith gradually seeing the light and coming to realize that they are basing their practice on an unstable theory, and if they will of themselves, with possibly some stimulation from the outside, raise the standards of their medical schools and of their personnel, the theory of osteopathy will gradually begin to disappear and the adherents of that cult may be found gradually recognizing that the treatment of disease and the responsibility for patients is based on a broad scientific and inclusive practice of medicine.

DR. CHARLES E HUMISTON, Chicago. Let me ask of the advocates of osteopathy. Do you wish the sort of investigation that is now being conducted by the Council on Medical Education and Hospitals? Will you welcome such an investigation that will not be hurried but will be complete to your satisfaction?

DR. WILLIAM C WOODWARD, Chicago. One thing alone in the history of osteopathy is sufficient to condemn it in the eyes of all intelligent, fair thinking men, and that is the utter unwillingness of the osteopaths to produce any evidence through animal experimentation of the truth of their theories. If there is any formal diagnosis and treatment that is susceptible of demonstration on animals, it is certainly that form which is advocated by the osteopathic school. And yet not only has no evidence of any experimentation by the osteopaths themselves been offered, but never have they invited a fair and impartial investigation of the truth of the dogma to which many of them have professed still to adhere by any scientific body appointed by any state legislature. Their progress in the legislatures of the states has been altogether political and in no sense or measure scientific. So far as this inspection is concerned it is quite possible to find things within a very few minutes that are sufficient to condemn the subject matter of the investigation. I imagine that this is what happened in the case of these schools. Osteopathy in its entire career has turned out practically no scientific literature of its own but depends on the books that are turned out by scientific medical men. One of the stronger opponents of the enactment of basic science laws has been the osteopaths for the reason that they recognized, I believe, the inadequacy of their men in the basic sciences. Their fears with respect to those laws are demonstrated by the fact that over a period of years, and over the experience of quite a group of nonmedical, unbiased basic science boards, 36 per cent of the applicants from osteopathic schools failed utterly as against 10 per cent of the medical men and medical students.

DR. E S RYERSON, Toronto. Dr Etherington merely picked out three or four paragraphs in the report. It would take over three or four hours to read all the details given in the report by Dr Etherington and myself. We did take down a fair amount of detail as to conditions in lectures, laboratories, clinics, and so on. It is hardly fair to judge what Dr Etherington has presented in this very limited time as the report. One of the speakers said he had read the report. I would like to know where he received it, because it has not as yet been published. It is still in the hands of the body for which it was made and has not been disposed of or made public in any way.

DR. FREDERICK ETHERINGTON, Kingston, Ont. There is nothing that I care to add except that the paper I prepared this afternoon was not supposed to be even a synopsis of the report. We have reams of material which we got by direct observation. They said we stayed four hours in Kirkville. We were there from 1 o'clock in the morning until 6 in the afternoon. How many hours is it going to take to size up a hospital with fifteen patients? I have been in touch with hospitals all my life here and abroad. Gross pathology doesn't exist in these schools. They don't teach it as far as I

could ascertain. They have no museums, they don't do post-mortems. In Des Moines they laid claim to only one post-mortem a year and that was done in an undertaker's establishment. So my feeling is that we spent too long in the inspection. We have got a certain number of facts, not opinions, and I challenge any one to controvert those facts. It isn't a matter of time. We have offered to osteopaths in Ontario precisely the same rights and privileges that the homeopaths have. Our friend is misinformed. There has been a change in government and they supplanted a medical man by an osteopath on the board of regents. But there hasn't been any change in the law. You know that the osteopath is not practicing osteopathy, he is practicing medicine and he wants to practice medicine. And he knows in his heart that this backbone theory of disease doesn't hold water. The homeopaths conform to our educational requirements. They take all the examinations as laid down by our statutes. We give them a special examination in homeopathy. We will do the same for you. Get the broad general training and we will give you a special examination. Is that fair?

DR DANIEL J. GLOMSET, Des Moines, Iowa. I am from Des Moines. Everything he said about our school is unfortunately true. I visited the hospital a number of times.

Trends in Graduate Teaching

DR CHARLES GORDON HEYD, New York. This article was published in full in THE JOURNAL, March 30 page 1061.

Postgraduate Work by the Iowa State Medical Society

DR DANIEL J. GLOMSET, Des Moines, Iowa. Iowa has felt the need for postgraduate instruction for some time. Thomas McManus of Waterloo in 1929 in his presidential address before the Iowa State Medical Society said: "In this state there are approximately 3,260 physicians practicing medicine. Of this number about 1,000 were graduated during the past ten years. That leaves a balance of 2,260 who have been ten years or more out of medical school. It is conservative to assume that 70 per cent of medical practice in Iowa is being done by physicians who were graduated ten or more years ago. Medicine, in a single decade, has made decided progress and it is just as important for the public welfare that physicians who have been a number of years in practice should enjoy the advantages of modern medicine as it is for the recent graduate to have had the last word in scientific attainment."

Dr McManus made arrangements with the University of Iowa faculty to conduct two trial postgraduate courses. One course was given by the department of obstetrics and one by the department of pediatrics. Each course consisted of twenty teaching hours. They were given weekly on two consecutive days in Waterloo and in Mason City, one following the other. The price of this instruction was \$10 for each course. The teaching was received enthusiastically. The next year the council of the state society appointed a committee of three physicians to direct the activities of the newly established speakers' bureau. The committee met and agreed on the following objectives in the program of educating the state of Iowa medically: (1) to increase the efficiency of the practitioner in Iowa, (2) to promote the solidarity of the profession, (3) to develop medical leadership in each community, (4) to educate the public in problems of health. To accomplish these objectives the following procedure was adopted: All work to be carried out through local medical units (a) by members of the faculty of the school of medicine of the state university (b) by members of the state society especially qualified for certain tasks, (c) by occasional distinguished outside talent.

This work the committee was told must be self supporting. Consequently the fees from the postgraduate courses had to be sufficient to pay the expenses of the bureau. As the enrolment for this work increased fees have been cut in proportion. The expenses of the speakers' bureau for the five years of its existence have been \$14,148.09 and the receipts \$17,526.52. After this program had been in effect two years the state society decided that the bureau had proved the worth of its activities and accordingly voted it an allowance from the budget which allowance has not been used up to the present time.

The speakers have all contributed without compensation. The bureau has paid them only their expenses, and in some instances even these have been refused by the men. In spite of the hardships connected with going from place to place, the teachers and the pupils again and again have expressed their enthusiastic approval. The work of the bureau covers five fields: (1) postgraduate courses, (2) scientific programs for medical groups, (3) clinics, (4) talks to lay audiences, and (5) radio talks. During the four years in which the bureau has been in existence there has been an enrolment in the postgraduate courses of more than 1,675 physicians, which is more than two thirds of the total membership of the state medical society. The bureau started out by offering only courses given by faculty members of the college of medicine of the state university. After two such courses had been given, the demand became so great that the university could not arrange enough courses without demanding too much of the time of the faculty members of the medical school. The bureau therefore organized other types of postgraduate courses in addition, namely: (1) those in which the lectures are given by prominent medical men from outside the state, and (2) those in which the lectures are given by outstanding private practitioners within the state. Many of the courses that have been given represent a mixture of two or three of these types of courses. Every department in the university except dermatology has taken part in the course. The men on the faculty have endeared themselves to the profession because of their faithful work for their fellow practitioners. Because these men are doctors first, last and always they are willing to take on the extra amount of work required for this teaching. It is to be hoped that the friendships they have made and the knowledge they have acquired by first hand observation of the problems of the practicing physician will aid them in their teaching and in some way compensate them for what they have so willingly given.

Because of decreased appropriations, the medical faculty is unable to provide the staff for more than two courses in the fall. Outstanding private practitioners within the state and prominent men from outside Iowa have been asked to do the work for the other courses. With few exceptions, the arrangements for these courses have been the same as for the university courses and the enrolment has been 515. Teaching by means of clinics has been used to a certain extent, in cooperation with the Iowa Tuberculosis Association, and these have reached more than 1,700 men in all parts of the state. Pediatric clinics, skin clinics and clinics dealing with other phases of internal medicine have also been conducted by the bureau. In spite of the fact that this work has been carried on during a period of financial stress, physicians have flocked to these courses. It is evident that the Iowa practitioners are anxious to make themselves better prepared for the practice of medicine. There is a marked increase in interest in scientific medicine, shown by more meetings than ever before, by better attendance and by better programs, there is an enormous increase in the output of literature from the state medical library, and there is a distinct increase in fraternal spirit because of the constant intermingling in meetings and postgraduate courses.

DISCUSSION ON PAPERS OF DRS HEYD AND GLOMSET

GEORGE B. ZIEGLER, M.A., University, Va. I accept in the main Dr Heyd's conclusions that there are three distinct phases of the problem of graduate medical education, namely: (1) research, (2) the training of specialists and (3) "the continuous and periodic reeducation of the general practitioner." I would enlarge on the third type of graduate instruction indicated by adding that the general practitioner needs to be further educated as well as reeducated. The term most generally employed in discussions of graduate medical education is 'postgraduate education' but it is obvious that this term is sometimes used to refer to only one of the three, at other times to two, and at still others to all three types of instruction under consideration. It will simplify the problem if terms that clearly distinguish between these three phases of graduate education are adopted and generally used in medical literature. It is dangerous to say which of these three types of graduate study is most important. However, the needs for research and for the education of specialists has been recognized for years. But the recognition of the problem of the continuing education of

the general practitioner is more recent, the undertaking is more extensive in scope, and resources in teaching facilities are and will have to remain more scattered. In practically every respect the problem is more difficult. Since my interests are distinctly in this phase of graduate education, I will devote the rest of my discussion to it. Dr Heyd said that the defect in medical practice today is the lag between scientific knowledge and practical application. He called attention to the rapid advancement in scientific knowledge so that within a ten year period a physician out of touch with sources of new knowledge may be incapable of practicing modern medicine. He included, too, most of the agencies that should aid in this educational program: (1) county and city medical societies, (2) traveling clinics, (3) two and three day clinics in the larger centers, (4) hospitals, (5) medical publications and (6) medical schools. I disagree, for sake of argument at least, with his conclusion that the systematic approach to overcoming this medical gap will be largely the obligation of universities conducting schools in graduate medical education. I think the principal responsibility rests on the local, state, sectional and even national medical societies and the hospitals. The universities and the medical schools should assume responsibility and a certain leadership and should cooperate with the other agencies working toward the desired goal, but the driving force must come from the medical societies, that is, from the physicians and the hospitals. The hospitals, owing to the rather uniform manner in which they are distributed through the country, are the strategic focal points in which most responsibility in offering instruction can be entered. A rather ideal approach to the problem of cooperation is found in Virginia. The state medical society, with the cooperation of the two state medical schools, sponsors a state-wide program of graduate education. The extension division of the University of Virginia is the executive agency of the society. Instruction is offered in any community only on approval of and in cooperation with the local medical society. But Virginia yet has much to learn about using local hospitals and local instructors and obtaining clinical materials for instructional purposes. Hospitals should take cognizance of the possibilities of the staff meeting as an agency for the continuing education or reeducation of the physicians in the vicinity of the hospital. The standards affecting hospitals set by the American College of Surgeons seem to me to strengthen this institution as an educational agency. They require that medical staffs be organized that complete records of cases be kept, that regular staff meetings be held and that staff members review and analyze their clinical experience. Hospitals should see to it that local physicians have the opportunity to utilize to the fullest the educational features of the staff conferences. As a layman I was interested in Dr Heyd's suggestion that somewhere and in some fashion the public must be considered and consulted. Machinery for communication in some intelligent manner must be established and kept smoothly functioning.

DR A S BEGG, Boston. In September 1933 the state society decided to offer to all the eighteen districts of the state a chance to obtain the type of postgraduate instruction which they appeared to want. These eighteen districts participated in this program the first year, which was completed last June. The registration fee was \$5. But the group in charge of this movement had one advantage over the Iowa group. The society gave it an appropriation of a thousand dollars to start with. The instruction last year was conducted in twenty-four centers and there were more than a thousand physicians enrolled for the courses. That is remarkable in view of the number of other things that are going on in our community. Recently it was reported to us that there are more than fifty organizations in the vicinity of Boston holding medical meetings of a regular character during the year. In fact, the situation has got so bad in Boston that I think I am quoting Dr Christian correctly when I say the one thing that cannot be promised an out-of-state speaker in Boston is a large audience. It may be enthusiastic but it won't be very large because there are a half dozen other meetings going on at the same time. The organization of these outside districts has been spectacular in the way in which the people have responded. The practice has been to try to anticipate what the men were interested in and in each case we have tried to have a liaison officer within the district. Sometimes this liaison officer was

the secretary. We sent out cards and tried to get the men to choose from the courses that were offered, but just a few weeks ago, before the meeting of the council of the Massachusetts Medical Society, there was a meeting of the presidents and secretaries of the district societies in which it was indicated that probably in the future these programs would have to be set by the districts themselves, acting through their officers rather than by the personnel of the district. I wish to mention the surprise of some of us in regard to the subjects that have been chosen. For example, a curious avoidance of any instruction on venereal diseases, and also, in spite of the propaganda that we have had, on psychiatry. The institutions that cooperate with us in this extension work are the state department of public health and the teaching faculties of Harvard University, Boston University and Tufts College Medical School. Some one said a few minutes ago that there ought to be some way to evaluate instructors, and this is what is happening in our case there. Some of these men are very enthusiastically received and occasionally we receive requests that a man be not returned to that community.

DR DANIEL J GLOMSET, Des Moines, Iowa. The thing that impressed itself on the committee is that some form of postgraduate instruction should become the rule for every practitioner. One thing that we have tried in Iowa, which possibly has not been tried in other places, is for the state society to keep the physician from going to sleep, as it were. We have employed more than 1,200 men. We do all of our lay education. The state society takes the position that it is the function of the doctors, as citizens, to educate the public in medical matters. We have used physicians to give lay talks, and in some of our higher institutions of learning we have actually had courses in health. We select doctors from all over the state to give these talks. In that way we have succeeded in keeping a large number of our youngsters up and coming.

Are Interns Practicing Medicine?

DR HAROLD RYPINS, Albany, N Y. Since an intern is expected to have the usual training and knowledge of the practicing physician and is engaged, more or less under supervision, in doing those things which ordinarily are done only by duly licensed physicians, the medical or common sense answer must necessarily be "Yes, the intern does practice medicine." From the point of view of the various medical practice acts however, the answer is an equally clear-cut "No." Legally speaking, the intern does not practice medicine. With the exception of the state of Indiana, where the rules of the board now require all interns to be duly licensed to practice medicine, I believe that all of the state laws governing the practice of medicine specifically exempt from the requirement of medical licensure interns or medical residents. There are four ways in which the status of the intern is classified. If the medical profession will arrive at a clear determination as to which of these states is the most desirable the various state laws can be amended to give the necessary legal sanction to the medical profession's views. These four possibilities are as follows: 1. The intern may be exempted from the requirements of licensure. At present this is the case in thirty-one states. 2. A medical license may be required as a condition precedent to internship. So far as I know, this is the case only in Indiana. 3. The internship may be required as a condition precedent to licensure. This is the present law in sixteen states as well as in the District of Columbia and Alaska. 4. Finally the internship may be a requirement for the medical degree. This is now the case in fifteen medical schools in this country and three in Canada. With the possible exception of Minnesota where the degree of Bachelor of Medicine, granted after the completion of four years of professional work, admits the holder to the Minnesota state licensing examination, although the final degree of Doctor of Medicine is not granted until the completion of a year's internship, this means that for practical purposes graduates of these eighteen schools must have the internship as a condition precedent to licensure whether or not such internship is a prerequisite in the state in which the candidate applies for licensure.

Were there any very marked advantages among these four plans it is probable that by this time overwhelming evidence would have led to a more general adoption of one system. In

the absence of such evidence, it is reasonable to conclude that one system appears to work about as well as another. Nevertheless there are certain theoretical advantages and disadvantages. In the first place, there is so great a unanimity as to the desirability of an internship in preparation for the practice of medicine that well over 95 per cent of all graduates now voluntarily undertake such training. It is evident that laws can accomplish relatively little in increasing the number of students taking internships. The disadvantages of having the internship as a state requirement for licensure have been apparent in many states in which this is the law. The state is not as competent as the medical school to regulate the details of professional training and the inelasticity of state laws and regulations constitutes a serious hindrance to effective administration.

The Indiana plan of requiring an intern to have a medical license is not practical, as there would be a considerable delay after the student's receiving his medical degree before he could obtain his license and begin his internship. In addition the large number of students who plan to receive their licenses through passing the examination of the National Board of Medical Examiners would be barred from internship, since the completion of the internship is necessary for obtaining the diploma of the National Board.

Little can be done to increase the number of available internships, which are not quite sufficient in number. Emphasis should be placed on better rather than more internships, that is, internships which are properly supervised for the systematic education of the interns. This can be done adequately only through incorporating the internship in the medical course necessary for the M.D. degree.

The five medical schools of New York City have joined with the Academy of Medicine to make a most extensive survey of the teaching possibilities of internships in New York City. The results of this survey should be a most important contribution to the problem and its conclusions a valuable guide in the matter.

My conclusion is that the proper law is one which states that the intern is not practicing medicine within the meaning of the statute. Ultimately either the medical schools themselves or the state boards will almost certainly require the internship as part of the fundamental training of the medical student, a prerequisite for both the medical degree and admission to the state licensing examination.

DISCUSSION

DR J. W. BOWERS, Fort Wayne, Ind. The practice of medicine is a state right, therefore a uniformity of law would be hard to attain because the problems in one locality might be diametrically opposite to the problems of another. The statute of Indiana does have a student's exemption clause but it was written long before the days of internships. "This act shall not be construed to prevent medical students from practicing medicine and surgery under the immediate and direct supervision of a licensed physician for a limited period. In no event shall the said student open an office or offer to engage in the practice of medicine, surgery or obstetrics." In recent years there were graduates from schools serving internships in Indiana that were not eligible for licensure and could never qualify for practice in the state. Therefore, in 1933 the board adopted a resolution that any physician who desires to serve as an intern in a hospital in Indiana shall be in possession of an Indiana license or shall present documentary evidence of having successfully passed the examinations of this board for a license, or the examination of a board of another state, which would entitle him to a license in Indiana through reciprocity. This does not pertain to a student from a college that requires the fifth year because he is not a physician but still a student. Beyond doubt, the intern year is the crowning feature in one's collegiate work. The hospital that gives the proper intern training is one that has a functioning staff on which the intern receives instruction, is allowed to view and assist in various capacities, and has rotating services. This intern is not practicing medicine within the meaning of the law but is still a student. Hospitals that give an improper training are hospitals in which the instruction is secondary. The interns receive maintenance and sometimes a small sum per month. They are

called on to give anesthetics, and the customary fee is collected and retained by the corporation. Another practice is that of emergency cases in which the intern assumes complete charge gives the service and patients return for subsequent treatment and dressings, but the cases are likewise paid for by the patient and the sum collected is retained in the institution's treasury. Perchance one of these cases might prove fatal. Who is going to sign the death certificate? Most certainly neither the intern nor the hospital. On their own initiative interns, nurses and employees in some hospitals do prescribe narcotics. When and by whom was this governmental authority given? The practice of medicine is a privilege and no corporation can obtain this privilege. Therefore these hospitals are aiding and abetting a fraud by having their interns and nurses violate the law by doing that which they have no right. In discussing this problem it seems that the solution lies in a better regulation and supervision of the hospitals available for internship. These violations should be corrected as one of the requisites for a hospital to be recognized as accredited for the proper training of interns.

DR T. J. CROWF, Dallas, Texas. In Texas, no exemption in the law is made for the intern. Any person who treats or offers to treat a disease of any order or any deformity, and charges for it is practicing medicine within the meaning of the present medical practice act. However, no notice is taken of the intern who is practicing in a properly supervised internship. To some extent an intern should be held responsible. For that reason he could be held responsible for practicing medicine, with the present state of the law, which provides that any person who receives money or other compensation, either directly or indirectly, for treating a human being for a disease or disorder is practicing medicine. I think that is a protection. I believe it is figuratively meant that every intern is practicing medicine when he completes his course and goes into a hospital. That is what he is there for.

DR HAROLD RAPINS, Albany, N. Y. I envy the gentlemen who live in western and southern states where apparently the law is flexible and can be enforced or not, according to the whim of the administrative officer. In New York we have to follow the law. But in general I think that as long as we say a license is not required we do not require it. However, if our law said that a license would be required every one who wanted to be an intern would have to have a license.

Uniform Standards of Licensure

DR CHARLES B. PINKHAM, Sacramento, Calif. A comparative study of the mechanics of licensure, as administered by boards created under the many medical practice acts of the United States, discloses such a lack of uniformity that one wonders what may be the ultimate solution. Its complexity is rapidly growing because of the allied problems of present-day medical practice. The number of medical schools in the United States has been reduced in the past decade, the requirements for admission have been advanced, enrolment has been limited and an intern year added, yet still the output of the American medical colleges is steadily increasing. Faced with overcrowded medical ranks and the economic distress, the medical graduate today is confronted with a situation that threatens his career as a practitioner of the healing art. In many states, after he has gained his right to practice in the form of a medical license the medical licensee must compete with those who possess diplomas bearing the name of nondescript schools.

The majority of boards authorized under the laws of various states to license the products of these nonmedical groups are none too exacting in the verification of the asserted credentials presented by applicants for a license. Thus is encouraged the forging of credentials, the purchase of diplomas, the activities of diploma mills and the too frequent scandals that besmear the fair name of the victim state because of the misdeeds of a few rascals. A uniform standard of licensure is the crying need.

Basic science legislation has been proclaimed as a solution to elevate the standard of the nonmedical group. A questionnaire distributed to the secretaries of all medical licensing bodies in the United States and returned completed by all except Delaware disclosed that only ten states reported a basic science law in operation. Only four states not having a basic science law reported that they favored such an enact-

ment A basic science law will not uphold the ideals for which it was created unless each member of the board of examiners created under it is fully qualified by completion of the entire resident course in an accredited university

The varying personnel composing medical examining boards may be of interest California has a (1) medical board composed of ten graduates of medical schools (2) an osteopathic board composed of five graduates of osteopathic schools and (3) a chiropractic board Eleven state boards have at least one osteopathic board member Mississippi and West Virginia each have a dentist member The District of Columbia board is composed of one M.D. and four laymen, Illinois reports a chiropractor member for examination only while the Indiana board has a chiropractor member Kentucky has a pharmacist as a board member

A medical graduate passes on the credentials of an applicant for a medical license in the majority of states A lay secretary validates credentials in Illinois, Nebraska New York and Washington, while in Massachusetts credentials are passed on by the chief clerk

Colorado, Georgia, Illinois Kentucky, Maryland Massachusetts, Pennsylvania Utah and Virginia, reported that they do not require the application to be accompanied with a medical diploma Some of these states will accept the certificate of the dean of the medical school in lieu of a diploma An applicant will be admitted to examination in Kentucky without a diploma if graduation is shown within one month after examination

An internship requirement either by law or board rule for admittance to examination was reported by Alaska the District of Columbia, Illinois Iowa, North Dakota, Oregon Pennsylvania South Dakota and Wyoming Washington reported that it admits to examination provided not more than six months is yet to be served to complete the applicant's internship The medical practice acts of sixteen states require completion of an internship before application for medical examination is acceptable Fifteen medical colleges require completion of an internship before a medical diploma will be granted

The urgent need for greater uniformity in standards of medical licensure is reflected in the methods used by various medical examining boards in evaluating credentials from foreign medical schools California has experienced great difficulties in verification of credentials from foreign countries The teaching system followed by foreign medical schools, their method of keeping record of attendance of the individual student, the basis on which is computed each scholastic term or year, their inability or refusal to furnish a tabulated record of the medical studies completed by a student his attendance and grades, and, worst of all that confusing European habit (universally prevalent in Germany) of attending four, five or six medical schools, all combine to form a perplexing problem for a state medical examining board Verification of medical credentials through the proper officer of German medical schools is practically impossible because of the political conditions Russia for years has been in such a state of political unrest that verification of medical credentials from that country has been impossible Puzzling as to authenticity are the average alleged official Russian documents filed by the graduate of a Russian medical college as his credentials Invariably written by hand or typed on a poor quality of paper these documents are far from acceptable evidence of medical qualifications The resolution passed by the Federation of State Medical Boards requiring all graduates of foreign medical schools to serve at least a one year internship in an approved United States hospital or to complete the senior year in an approved United States medical school appears from our questionnaire to be enforced by only one medical examining board The influx of foreign physicians now acute will be a more perplexing problem when the 1,500 Americans reported last year as having gone to foreign countries to study medicine return to our shores in search of a medical license Faced by the uncertainties of credentials from foreign medical schools Alaska Arizona, Georgia Kentucky Louisiana, Mississippi and North Carolina reported that foreign credentials were not accepted and that foreign graduates were not admitted to examination Some state medical boards permit a foreign applicant special privileges New Mexico permits the use of an interpreter

during the examination He is selected by the board, is seated with the applicant in the same room with other applicants and is permitted to refer to books Because this interpreter may be a graduate of a medical school it is conceivable that, fortified by reference books which he is permitted to use during examinations he can be of great help to an applicant for a medical license Texas also permits the applicant to write in a foreign language and he is permitted to use an interpreter This interpreter is usually a board member a graduate of a medical college, is seated with the applicant in the same room as other examinees, and may refer to books Fourteen state boards reported that citizenship is not a requirement for admittance to examination for a medical license however, twelve require that first papers be held Two states require "declaration of intent" to become a citizen before the foreign graduate is admitted to examination Maryland permits distinguished foreign practitioners to be licensed by endorsement of their foreign credentials New York may also grant to graduates of foreign medical schools a medical license by endorsement whenever the applicant has been in practice in a foreign country for ten or more years In THE JOURNAL, Sept. 29, 1934, page 1015, was a list of 105 graduates of foreign schools, applicants for a New York medical license Thirty-nine passed and nineteen failed the written examination, while forty-seven of this group were licensed on endorsement of their foreign credentials

The mechanics of written examination procedure followed by medical examining boards is widely divergent Illinois appears to be the "Santa Claus" for all applicants because it reported that no application fee is required until the "applicant has been notified that he has been successful" A photograph of the applicant attached to his application is recorded as the universally adopted method of identification Had the Georgia board "checked in" applicants by photographs the asserted impersonation of Philip Dymont by Lucian Wright, reported to have written the examination for Dymont, would have been impossible Three state boards report a 'check in' by number only Eleven report that they require that the photograph of the applicant shall be in sight on his desk during his entire examination This is collected by tellers after the examination has been completed The Department of Licenses of Washington made no mention that a photograph of the applicant was required either attached to the application or otherwise

North Carolina reports that it is discretionary with the board as to the kind of examination given Twelve states reported that they offer more questions than the applicant is required to answer thus giving him opportunity for selection California offers twelve questions, the applicant being required to answer any ten Thirty-one states reported that they offer only a written examination Four states reported that bedside examination is required Some state boards reported that the questions of examination are prepared by board members a month prior to the date of the examination, while New York prepares the questions one year in advance of examination In such instances the custodian of examination questions bears a grave responsibility The custodianship of these valuable records varies in the several states Many examining boards place the obligation of protecting these questions from being known in advance on the secretary of the board

A passing grade of 75 per cent is established by practically all medical examining boards although Kentucky and New Mexico report 70 per cent as their passing grade, while Georgia, North Carolina, Rhode Island and West Virginia require 80 per cent The right to a review of the papers of those applicants who fall below the established passing grade is granted under certain conditions by twenty-three state boards Twenty-two boards voiced disapproval of an oral examination requirement for reciprocity applicants, eleven were favorable to such a requirement An interesting sidelight to our survey developed when all were unanimous in voting no to the query as to whether medical examining boards should examine and license in any of the specialties in medicine Because of the wide variation in the state medical practice acts the factors involved in their administration and the ever changing personnel of the average board of medical examiners the Federation of State Medical Boards can point with pride to the present standards of medical licensure

This digest of the survey indicates the need to press on. Consideration of the problems of other boards will broaden our administrative point of view.

DISCUSSION

DR J. N. BAKER, Montgomery, Ala. Any one who attempts to compare the laws in the various states is impressed with their polyclot, incongruous nature. I believe those things will be perfected slowly and gradually, as the educational forces get over to the public and to the legislatures. I consider the work of the National Board of Medical Examiners a great driving factor in this educational work.

DR J. C. MCINTYRE, Lansing, Mich. I have found no class A American medical schools that will accept a foreign graduate in the last year of medicine so Michigan is not bothered much with foreign graduates. We have had the same trouble that Dr. Pinkham has quoted in trying to evaluate foreign credits. It is almost an impossibility. There have been many spurious credits or credentials offered to us in the past. Michigan admits to its board only graduates of class A American schools who have served one year of rotating internship in an approved American hospital. Therefore it makes the problem easier in Michigan.

DR JOHN Z. BROWN, Salt Lake City. I should like to have Dr. Pinkham clarify his statement regarding basic science laws. In Utah some men are considering that problem. In Minnesota and other states with which we reciprocate they have it but we have not adopted it and it would require legislative action to do it.

DR T. J. CROWE, Dallas, Texas. I think there should be more discussion from the floor. If our work is worth anything at all if it means anything either to the medical profession or to the public, why not make it valuable one way or the other if we cannot both ways. I find that a number of the states go off independently and adopt a basic science law. A number of the basic science states have required that any applicant for reciprocity must take the basic science examination before reciprocity for that state can be granted. It is one of the tragedies of medical judgment that any state should adopt a basic science law without taking notice of the reputable graduate of ten years ago who had all the basic science subjects and who to get that reciprocal license must go back and review work that he did years ago. Arkansas told me that one of our men who went there could not qualify. This graduate had the basic sciences three different times in his academic two years of premedical education in his medical college and we gave them to him in our examination. How many times should he be expected to take the basic science examination? Why medical men will not look beyond the boundaries of their own state I cannot understand. Many boards are in disrepute because one state has one law and the neighboring state has another. Texas has one license certificate, and every man who practices medicine whether he is a drugless man or what-not conforms to the same law and is examined in the fundamentals of medicine and the basic sciences.

DR CHARLES PINKHAM, Sacramento, Calif. Answering the question of the member of the Utah board I did not mean to convey the impression that there was to be a national basic science law. What I tried to make clear was what Dr. Crowe has been talking about, that the well educated individual, having obtained his license in one state, should not be required in going to a sister state to pass a basic science examination. California recently had a similar experience with the state of Washington. A graduate of the University of California, a class A institution, with an A.B. degree and a California medical practice certificate, after a written examination could not get into the state of Washington until he had passed the basic science examination. That is absurd. I tried to stress in my paper that, because California has the chiropractic and the osteopathic boards created by an initiative measure that is, by a vote of the people any legislative enactment of a basic science law by the state of California would be absolutely valueless. However, if such a basic science law is passed by initiative, it would require all who present themselves to either of those two boards to have the basic science certificate first. And that is the only method whereby basic science can be available in the state of California.

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45 Chicago daylight saving time (3:30 p.m. central standard time). The next three broadcasts will be delivered by Dr. W. W. Bauer. The titles will be as follows:

May 9 Saving Our Mothers
May 16 Children's Eyes
May 23 Saving Our Eyesight

National Broadcasting Company

The American Medical Association broadcasts under the title 'Your Health' on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15 Chicago daylight saving time (3 p.m. central standard time). The next three broadcasts will be as follows:

May 7 Mothers of America W. W. Bauer, M.D.
May 14 Training Good Doctors W. D. Cutter, M.D.
May 21 Pain W. W. Bauer, M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

State Medical Meeting in Yosemite—The sixty-fourth annual meeting of the California Medical Association will be held at the Ahwahnee Hotel Yosemite National Park, May 13-16 under the presidency of Dr. Clarence G. Toland, Los Angeles. There will be general sessions each morning, at which the following will speak:

Dr. Edward Starr Judd, Rochester, Minn., Research in Medicine—Practical Applications.
Dr. George H. Whipple, Rochester, N.Y., Anemias, Experimental and Clinical.
Dr. Thomas P. Sprunt, Baltimore, Md., Medicinal Treatment of Hepatic and Biliary Disorders.
Dr. James S. McEster, Birmingham, Ala., President Elect, American Medical Association, The Profession's Economic Responsibility.
Lionel Browne, San Francisco, deputy attorney general, The Right to Regulate and the Reason for Regulation of Professions.
Paul A. Dodd, Ph.D., Los Angeles, director of the association's survey of medical service, Pertinent Facts Uncovered by the State Survey of Medical Service.
Dr. Harry H. Wilson, Los Angeles, What Is the Remedy?

In addition there will be guest speakers at the section meetings as follows:

Dr. Whipple, Regeneration of Hemoglobin and Plasma Proteins as Related to the Liver.
Dr. Sprunt, Acute Disorders of the Liver.
Dr. Judd, Surgical Treatment of Lesions of the Stomach and Duodenum.
Dr. Byrl R. Kirklin, Rochester, Minn., Clinical Indications for Roentgenologic Studies of the Stomach.
Drs. Paul G. Flothow and Sylvester N. Berens, Seattle, Diagnostic and Alcohol Injection of the Sympathetic Nerves.
Dr. Ralph M. Towell, Rochester, Minn., Modern Trends in Anesthesia.
Dr. Charles U. Moore, Portland, Ore., Incidence of Rachitic Imperfections in Children.
Dr. Henry Schmitz, Chicago, A Comparison of 600 Kv. with 200 Kv. Roentgen Ray.
Dr. LeRoy Sante, St. Louis, Roentgenologic Differentiation Between Acute Intestinal Obstruction and Paralytic Ileus.

Dr. Frederick C. Warnshuis, San Francisco, secretary of the association and speaker of the House of Delegates of the American Medical Association, will address the sixth annual meeting of the Woman's Auxiliary of which Mrs. Philip Schuyler Doane, Pasadena, is president.

CONNECTICUT

Highway Named for Beaumont—The Connecticut legislature has authorized a new highway between Lebanon and Willimantic to be named the Beaumont Memorial Highway, in honor of Dr. William Beaumont, pioneer in the study of the physiology of digestion. Dr. Beaumont was born in Lebanon, where the Beaumont Society of Connecticut erected a memorial some years ago. Dedication of the new highway will take place June 1 with ceremonies at which Gov. Wilbur L. Cross and Dr. Harvey Cushing will make addresses.

University Appointments—Mark A. May, Ph.D. executive secretary of the Institute of Human Relations at Yale University, New Haven since 1931, has been appointed director of the institute. President James Rowland Angell has been director. Dr. May came to Yale from Columbia University, New York in 1927 as professor of educational psychology. Dr. Leonard Greenburg, health officer of New Haven has been promoted to be associate clinical professor of public health, and Dr. Chris Harold Neuswanger to be assistant clinical professor of urology. Dr. Robert Tennant Jr. has been made assistant professor of pathology and Gertrude Van Wagenen, Ph.D., assistant professor of obstetrics and gynecology.

FLORIDA

Bills Passed—The following bills have passed the senate S 141, proposing that whenever the word physician appears in any law unaccompanied by any descriptive language denoting some particular kind of "physician," it shall mean a licentiate of the State Board of Medical Examiners or a licentiate of the State Board of Osteopathic Medical Examiners, S 144 proposing to amend the medical practice act by making it the specific duty of all sheriffs, constables, their deputies, police officers, peace officers, prosecuting attorneys, and the state board of health to enforce the provisions of the medical practice act. S 145, proposing to amend the narcotic drug act by permitting osteopaths to administer and prescribe narcotic drugs. S 146, proposing to amend the medical practice act by requiring an applicant for a license to practice medicine to be a citizen of the United States, rather than, as the present law requires to be a citizen of the United States or to have declared his intention to become a citizen.

Bills Introduced—S 148 and H 145 propose to accord to hospitals, physicians, osteopaths, chiropractors, naturopaths and nurses, treating persons injured through the fault of others, liens on all rights of action claims judgments compromises or settlements accruing to the injured persons by reason of their injuries. S 238 proposes to require the state board of health to distribute insulin free of cost to indigent residents of the state suffering from diabetes or kindred diseases that require the use of the drug. H 91 proposes to repeal the existing naturopathic practice act and to enact a new naturopathic practice act. The bill proposes, in effect, to extend greatly the scope of a license to practice naturopathy. It purports to permit licensed naturopaths, in addition to the practice now permitted to practice physiotherapy, herb therapy, electrocoagulation and electrotherapy. It also removes the express provision in the existing law prohibiting naturopaths from practicing materia medica or surgery. H 147, to amend the law requiring physicians to register annually with the state board of health and to pay a fee of \$1 proposes that, after a physician has once registered with the board and paid a fee of \$2, he need not reregister until such time as he changes his residence or the place in which he intends to carry on the practice of medicine. H 149 proposes to prohibit all persons, other than licensed physicians and licensed osteopaths from prescribing drugs, doing surgery, x-ray, diathermy, electrocoagulation, radiation, or autohemotherapy in the diagnosing treatment operation or prescribing for any human disease, pain, injury, deformity or physical condition. H 494 proposes to require that all persons in the state over the age of 4 be vaccinated and immunized against smallpox.

GEORGIA

Society News—At a meeting of the Fifth District Medical Society in Atlanta, March 29, speakers included Drs. Stewart R. Roberts on 'Treatment of Congestive Heart Failure', William M. Scruggs, Charlotte N. C. 'Management of the Toxic Goiter', Thomas C. Davison 'Surgical Treatment of Angina Pectoris' and Louis G. Herrmann, Cincinnati 'The Passive Vascular Exercise (Pavac) Method of Treating Obliterative Arterial Diseases of the Extremities'.—The Georgia Academy of Science was addressed at its annual meeting, March 22-23, among others by Clinton C. Howard, D.D.S., Atlanta, on 'Two Sets of Identical Twins Presenting Identical Anomalies'. Drs. George L. Kelly, Augusta 'The Direct Observation of Ovulation in the Rabbit', Homer R. Blincoe and John H. Venable, Emory University 'Persistence in Man of An Aortic Arch Resembling That Which Persists in Adult Reptiles' and Joseph H. Kite, Decatur 'Nonoperative Versus Operative Treatment of Tuberculosis of the Spine in Children'.—At a meeting of the Fulton County Medical Society, March 7, Dr. Frank Lee Bivings presented a paper on 'The Feet in Infancy and Childhood'.

ILLINOIS

Bill Introduced—H 863 proposes to limit the sale of appliances, articles, drugs or medicinal preparations intended or having special utility for the prevention of conception or venereal disease to persons licensed by the department of registration and education to sell them.

Personal—Dr. George A. Zeller has retired as superintendent of the Peoria State Hospital, a position he had held consecutively since 1921 when the institution was being organized in 1898. Dr. Zeller was named superintendent but did not assume active charge until 1902, continuing until 1914, when he became alienist for the board of administration.—Dr. John R. Neal, Springfield, a former president of the Illinois State Medical Society has been named medical director of the Alliance Life Insurance Company.—Dr. Albert F. Fritze, Chester, observed his fiftieth anniversary in the practice of medicine, March 15.

CHICAGO

Dr. Vallery-Radot Lectures—Dr. Pasteur Vallery-Radot, associate professor of medicine, University of Paris Faculty of Medicine, and physician to the Bichat Hospital, presented a lecture April 28 at the Casino on 'La vie intime de Pasteur'. The lecture was under the auspices of the executive board of the American Library in honor of Pasteur.

Portrait of Dr. Parker—An enlarged photograph of the late Dr. Charles A. Parker was presented to the Chicago Orthopedic Society by Dr. Daniel H. Levintal at a meeting, April 12. The portrait was donated by the Huey Company to Dr. Levintal for the society. It will be hung in the children's orthopedic ward at Cook County Hospital, where Dr. Parker worked for many years. Dr. Parker died July 16, 1934.

IOWA

State Medical Meeting at Davenport—The eighty-fourth annual session of the Iowa State Medical Society will be held in Davenport, May 8-10 under the presidency of Dr. Gordon F. Harkness, Davenport and with headquarters in the Masonic Temple. Out of state speakers will include:

Dr. Loyal Davis, Chicago, Treatment of Craniocerebral Injuries
Dr. William S. Middleton, Madison, Wis., Postoperative Pulmonary Complications, Their Prevention and Management
Dr. Harry S. Grable, Chicago, Management of Eye Injuries by the General Practitioner
Dr. Charles Anderson Aldrich, Winnetka, Ill., Treatment of Acute Nephritis in Children
Dr. James S. McLeister, Birmingham, President Elect, American Medical Association, Deficiency Disease as a Clinical Problem

A symposium on carcinoma of the colon will be presented Wednesday morning, Wednesday and Thursday afternoons will be given over to sectional conferences for discussion of the specialties. In addition, papers will be presented during the morning sessions by Iowa physicians. Entertainment will include a smoker Wednesday evening at the Blackhawk Hotel and the annual banquet Thursday evening with Dr. Frank B. Dorsey Jr., Keokuk, as toastmaster. Dr. Harkness will deliver his presidential address at the banquet and the president-elect, Dr. Thomas A. Burcham, Des Moines, will also speak. A pre-convention golf tournament will be held Tuesday afternoon. The sixth annual meeting of the Woman's Auxiliary of the state society and the thirty-seventh annual session of the State Society of Iowa Medical Women will also be held at this time.

KENTUCKY

Graduate Course in Pediatrics—A ten weeks course in pediatrics is being given at the Children's Free Hospital, Louisville, under the auspices of the American Academy of Pediatrics. The teaching staff includes Drs. Philip F. Barbour, Thomas Cook Smith, James H. Pritchett, Annie S. Veece, James W. Bruce, William W. Nicholson, Jacob J. Glaboff and Harry S. Andrews. The course began April 24 and is to continue on succeeding Wednesdays through June 26.

MARYLAND

The Thayer Lectures—The eighth course of lectures under the William Sydney Thayer and Susan Read Thayer Lectureship in Clinical Medicine was delivered by Dr. Pasteur Vallery-Radot, associate professor of medicine at the University of Paris Faculty of Medicine, April 25 and 26 at Hurd Memorial Hall, Johns Hopkins University, Baltimore. Dr. Vallery-Radot's subjects were 'The Links Between Pasteur's Discoveries (From Molecular Dissymmetry to Antibiotic Vaccination) and From Experimental Anaphylaxis to Human Anaphylaxis'. The Thayer Lectureship was founded in 1927 by friends and admirers of the late Dr. Thayer.

Johns Hopkins Hospital Appeals for Funds—For the first time in many years, Johns Hopkins Hospital has opened a campaign for funds to carry on its charity work. The campaign was launched at a banquet at the Hotel Belvedere, April 23, at which Isaiah Bowman, Ph.D., recently chosen president-elect of Johns Hopkins University, made the principal address. Dr. Hugh H. Young, professor of urology in Johns Hopkins University School of Medicine and head of the Brady Urological Clinic at the hospital, is chairman of a committee to ask persons outside of Baltimore to contribute. The fund of \$200,000 that is sought will enable the hospital to carry on its charity work for two years and to open beds now closed in the children's surgical ward and the women's clinic, it was said. About 300 persons attended the dinner.

MICHIGAN

Memorials to Former Faculty Members—Three former members of the faculty of the University of Michigan School of Medicine were memorialized when relatives recently donated plaques to the university in their honor. The Albion Walter Hewlett Memorial Plaque will be placed in the University Hospital in honor of Dr. Hewlett who was professor of internal medicine and director of the clinical laboratories in the medical school, 1908-1916. It is the gift of Mrs. Hewlett now of San Francisco. Other plaques honor the memory of Dr. James G. Van Zwaluwenburg, who at the time of his death in 1922 was professor of roentgenology and Dr. George Edward Frothingham, who at the time of his retirement was professor of internal medicine, ophthalmic and rural surgery and clinical ophthalmology. These plaques were the gifts of Dr. Cornelius Van Zwaluwenburg, Riverside Calif., brother of the late physician, and the son of the late Dr. Frothingham, Dr. George E. Frothingham, Detroit. The late Dr. Van Zwaluwenburg was a member of the faculty from 1908 to 1922, and Dr. Frothingham from 1867 to 1889.

Society News—A joint meeting of the Wayne County Medical Society with the medical societies of Essex and Kent counties of Ontario, Canada, March 11, was addressed by Drs. George H. R. Hamilton, Chatham, on "Some Pitfalls in Diagnosis of Acute Abdominal Conditions", Chas. S. Sanborn, Windsor, "Relation of Duodenal Mucosa to the Natural Secretion of the Pancreas", William R. Waddell, Windsor, "Ulcerated Colitis", and Charles C. White, Chatham, "Acute Suppurative Arthritis".—Dr. Richard C. Connelly, Detroit, discussed "Gastric Secretion in Health and Disease" before the Grosse Pointe Medical Club, March 6.—At a meeting of the Detroit Oto-Laryngological Society, March 20, Dr. Clifford T. Brunk read a paper on focal infection.—At a meeting of the Genesee County Medical Society in Flint, March 6, Dr. Frederick C. Kidner, Detroit, spoke on "Anatomy of the Lower Part of the Spine in Relation to Pain".—Dr. Raphael Isaacs, Ann Arbor, discussed "The Mechanisms of the Formation of the Different Kinds of Blood Cells in Health and Disease" before the Detroit branch of the Society of American Bacteriologists, March 27.—Dr. Henry A. Luce, Detroit, addressed the Jackson County Medical Society in Jackson, March 19, on "Neuropsychiatry for the General Practitioner".—Dr. Max Cutler, Chicago, discussed "Diagnosis and Treatment of Cancer of the Breast" before the Wayne County Medical Society, Detroit, March 4.—Dr. Hartler L. Keim, Detroit, among others, spoke before the Bay County Medical Society, February 27, on "Skin Eruptions of the Face."

MISSOURI

State Medical Meeting at Excelsior Springs—The seventy-eighth annual meeting of the Missouri State Medical Association will be held at Excelsior Springs, May 6-9, at the Elms Hotel. Guest speakers and their subjects will be:

- Dr. John S. Coulter, Chicago, Physical Therapy in Chronic Arthritis
- Dr. Oswald S. Lowsley, New York, New Developments in Renal Surgery
- Dr. Roscoe G. Lehnd, Chicago, Medical Care for the American People
- Dr. Cecil S. O'Brien, Iowa City, will conduct an ophthalmic diagnostic clinic at the Veterans' Administration Facility at Excelsior Springs, and Dr. William W. Bauer, Chicago, will address the Woman's Auxiliary on "Centuries of Progress in Medicine." Among the Missouri physicians who will participate are:
- Dr. John R. Caulk, St. Louis, Chronic Pyelonephritis in Children
- Dr. Peter T. Bohan, Kansas City, Quinidine Sulphate: Its Actions and Uses
- Dr. Fred W. Bailey, St. Louis, Early Diagnosis in Obscure Abdominal Diseases
- Dr. Samuel H. Snider, Kansas City, Diagnosis and Nonsurgical Treatment of Bronchiectasis
- Dr. Ralph A. Kinsella, St. Louis, Treatment of Chronic Arthritis

- Dr. Frank C. Neff, Kansas City, Changing Practices in Infant Feeding
- Dr. Joseph V. S. Dauksys, Excelsior Springs, Schuller-Christian Disease
- Dr. George Wilse Robinson, Kansas City, Practical Factors in Development of Psychoses
- Dr. Titus S. Lapp, Fulton, An Institutional Outbreak of Shiga Dystrophy and Its Control
- Dr. Joseph S. Summers, Jefferson City, Myasthenia Gravis
- Dr. Casus T. Ryland, Lexington, will give his presidential address and Dr. Edwin Lee Miller, Kansas City, his address as president-elect, Tuesday morning, May 7.

NEW MEXICO

Institute on Venereal Disease—Dr. Walter Clarke of the staff of the American Social Hygiene Association conducted an institute of venereal disease at the Charles F. Lummis Hospital at the U. S. Indian School, Santa Fe, March 18-19, assisted by Dr. Robert H. Heterick, Albuquerque, medical director of District No. 3 of the Indian Medical Service. Twenty physicians and forty nurses attended.

NEW YORK

Society News—Dr. Charles T. Porter, Boston, addressed a joint meeting of the Syracuse Academy of Medicine and the Syracuse Eye, Ear, Nose and Throat Club, March 17, on "Etiology and Treatment of Infections of the Orbit".—Dr. Harrison S. Martland, Newark, N. J., and Alexander O. Gettler, Ph.D., addressed the Onondaga Medical Society and the Onondaga County Bar Association at their annual dinner meeting in Syracuse, April 13, on "Medical Detection of Crime" and "Chemistry in the Detection of Crime," respectively.—Drs. Henry L. K. Shaw and John E. Heslin discussed medical and surgical aspects respectively, of "Urinary Infections of Childhood" at a meeting of the Medical Society of the County of Albany, April 24.

New York City

Hospital Council Named—Members of an advisory council to coordinate the activities of hospitals were named by Dr. Sigismund S. Goldwater, commissioner of hospitals, March 29. As reported in the *New York Times*, they include Mayor La Guardia, Controller Taylor, Dr. Goldwater, Health Commissioner John L. Rice, Charles C. Burlingham, president of the Welfare Council of New York, Solomon Lowenstein, representing Jewish philanthropic agencies, Rev. Joseph S. O'Connell, representing Catholic Charities, Dr. John A. Hartwell, director of the New York Academy of Medicine, and Dr. David J. Kaliski, representing the five county medical societies.

Annual Art Exhibit—Two hundred and fifty nine exhibits were displayed in the eighth annual exhibition of the New York Physicians' Art Club at the New York Academy of Medicine, March 30-April 13. Only one of the number was on a medical subject, most of the work showing vacation scenes. The exhibit included printings, bas-reliefs, plaques, sculpture and photographs. Among the exhibitors were Drs. Howard Lilienthal, Henry H. M. Lyle, Louis C. Schroeder, Winfred Morgan, Hartshorn, Theron W. Kilmer, Walter Beran Wolfe, Yolande E. H. Huber, Alfred Braun and Abraham L. Wolbarst, all of New York, Frederic J. Cotton, Boston, and Florence A. B. Brush, White Plains.

Census of Diabetic Patients—The New York City Department of Health recently sent a letter to all physicians in the city asking them to inform the department of the number of diabetic patients under their care. The department is making an effort to place all persons with diabetes under the care of licensed physicians, as it has been found that many of them trust to nostrums, trick diets, alleged substitutes for insulin and the like, Dr. John L. Rice, health commissioner, said. Information assembled by the New York Diabetes Association indicates that there are as many as 100,000 diabetic persons in the city. It is believed that diabetes is more prevalent than tuberculosis.

NORTH CAROLINA

Bill Introduced—S. 504 proposes to require every male applicant for a license to wed, as a condition precedent to obtaining such license, to present a certificate of a licensed physician, executed within seven days of the application, that the applicant does not have any venereal disease or tuberculosis in an infectious stage and that he has not been legally adjudged to be an idiot, imbecile or of unsound mind. Female applicants are to be required to present a physician's certificate showing the nonexistence of tuberculosis in the infectious stages and that they have not been legally adjudged to be of unsound mind.

State Medical Meeting at Pinehurst—The eighty-second annual session of the Medical Society of the State of North Carolina will be held at Pinehurst, May 6-8, with headquarters at the Carolina and under the presidency of Dr Paul P. McCain, Sanatorium. There will be four general sessions, at which speakers will be the following:

Dr James R. Young, Anderson, S. C., My Experience in 2,200 Cases of Appendicitis
Dr Lester A. Crowell, Jr., Lincolnton, Pneumothorax Treatment of Lobar Pneumonia
Dr Russell O. Lyday, Greensboro, Surgical Treatment in Noncollapsible Cavities
Dr Williamson Z. Bradford, Charlotte, Factors Influencing Maternal Mortality in North Carolina
Dr David R. Lyman, Wallingford, Conn., Pregnancy and Tuberculosis
Dr Roy B. McKnight, Charlotte, The Charlotte Medical Library
Dr Franklin C. Smith, Charlotte, Conservation of Vision and the General Physician
Dr John Roy Hege, Winston-Salem, A Proposed County City Venereal Disease Program
Dr Verling K. Hart, Charlotte, Bronchoscopy in Childhood

In addition, Dr William Thornwall Davis, Washington, D. C., will address the section on ophthalmology and otolaryngology on "Treatment of Squint by Orthoptic Training and Surgery"; Dr Louis H. Clerf, Philadelphia, the section on practice of medicine, "Bronchoscopy as an Aid in the Diagnosis of Pulmonary Diseases," and Dr Jean P. Pratt, Detroit, the section on gynecology and obstetrics, on "Application of Endocrinology to Gynecology." There will be a golf tournament Tuesday afternoon, and the president's reception and ball will be held Tuesday evening. The Woman's Auxiliary will hold its annual meeting at the same time and the North Carolina Public Health Association will meet Monday, May 6.

OHIO

Graduate Assembly at Youngstown—The Mahoning County Medical Society presented its eighth annual graduate assembly, April 25, at Youngstown. Lecturers were from Rochester, Minn., as follows:

Dr Walter C. Alvarez, Treatment of Gastro-Intestinal Neuroses. Diagnosis of Gastro-Intestinal Disease Purely from a Good History
Dr Claude F. Dixon, Rectal Cancer. Management and Prognosis. Essential Operation for Chronic Ulcerative Colitis
Dr Frank C. Mann, Functions of the Liver. Functions of the Spleen
Dr Henry W. Meyerding, Clinical Aspects of Fibrosarcoma of the Soft Tissues of the Extremities. Spondylolisthesis as a Factor in the Cause of Backache

Society News—Dr Rosco G. Leland, Chicago, director, Bureau of Medical Economics of the American Medical Association, addressed the Toledo Academy of Medicine, March 1, on "Proposals and Developments Toward Sickness Insurance."—Dr Jesse O. Arnold, Philadelphia, addressed the Montgomery County Medical Society, Dayton, April 19, on "Dehydration Treatment of Eclampsia."—Dr Charles C. Higgins, Cleveland, addressed the Cincinnati Academy of Medicine, April 1, on "Experimental Production and Management of Renal Calculi."—Paul Nicholas Leech, Ph.D., Chicago, secretary of the Council on Pharmacy and Chemistry of the American Medical Association, addressed the Columbus Academy of Medicine, March 25, on "The Physician and His Drugs."—Dr Richard H. Jaffe, Chicago, discussed Malignancies of the Lung at a meeting of the Mahoning County Medical Society, March 19.—Dr Raymond E. Paul, Botkins, addressed the Shelby County Medical Society, Sidney, March 1, on trichinosis.—Dr John F. Beachler, Piqua, spoke on Early Diagnosis and Prophylaxis of Female Genital Carcinoma before the Miami County Medical Society, Troy, March 8.—Drs Kenneth C. McCarthy, Toledo, Floyd T. Romberger, Lafayette, Ind., and Alexander S. McCormick, Akron, presented a symposium on anesthesia before the Summit County Medical Society, Akron, April 2. The society's second "Post-Graduate Day" was held at the People's Hospital, April 17. Subjects presented were compression fractures of the spine, pneumonia, bronchial asthma, birth injuries, Hodgkin's disease and otitis media.

PENNSYLVANIA

Annual Clinic at New Kensington—The Westmoreland County Medical Society will hold its annual clinic at New Kensington, May 23. Drs Russell L. Haden, Cleveland, and Arthur M. Shipley, Baltimore, will conduct clinics and Drs Moses Behrend, Philadelphia, president, and Alexander H. Colwell, Pittsburgh, president-elect of the Medical Society of the State of Pennsylvania, will make addresses. Other speakers will be:

Dr Walter M. Bortz, Greensburg, Juvenile Diabetes
Dr Robert H. Jeffreys, Uniontown, Fractures of the Vertebrae
Dr John B. McMurray, Washington, Vertigo
Dr Horace B. Anderson, Johnstown, Cardiac Pain in Heart Disease
Dr George A. Holliday, Pittsburgh, Treatment of Gonorrhea

In the evening there will be a banquet at the Hill Crest Country Club.

Bills Introduced—S. 965 proposes to authorize a licensed optometrist to execute any certificate of ocular conditions or visual efficiency required by any law of the commonwealth. H. 2494 proposes to prohibit the marriage of persons who have been legally declared to be either weak-minded, habitual drunkards or lunatics. The bill proposes a procedure for the annulment of such marriages. H. 2500, to amend the laws regulating the practice of osteopathy, proposes to dispense with the present requirement that applicants for a license to practice osteopathy must have acquired a high school education prior to their osteopathic studies by requiring such applicants to have acquired a high school education prior to the time they apply for a license. H. 2502, to amend the law prohibiting the procuring of an abortion, proposes that "if it be found absolutely necessary to save the life of a woman who is pregnant and upon due certification by two licensed physicians at least one of whom shall be a member of staff of a state-aided hospital, that in their best judgment such is the fact, it shall not be unlawful to procure such miscarriage providing that such operation be performed in a state-aided hospital." H. 2531 proposes that hospitals receiving state aid shall, as a condition to receiving any aid, transmit to each regular session of the general assembly a full and complete statistical and financial report for the last two of its fully completed fiscal years. H. 2637 proposes that the state compensate physicians treating persons bitten by or directly exposed to an animal which in the opinion of a licensed veterinarian is afflicted with or has the appearance of being afflicted with rabies or is found to have been so afflicted by laboratory examination made by the department of agriculture, and to require the department of health to supply without cost sufficient antirabic serum for the treatment of such persons.

Philadelphia

Dr Burr Receives Strittmatter Award—Dr Charles W. Burr, professor emeritus of mental diseases at the University of Pennsylvania School of Medicine, received the twelfth annual Strittmatter Award of the Philadelphia County Medical Society, April 17. Dr Burr was graduated from the university school of medicine in 1886 and served on the faculty from 1901 until his retirement in 1931. He was neurologist to the Philadelphia General Hospital from 1896 to 1931 and was for many years on the staffs of the Orthopedic Hospital and the Infirmary for Nervous Diseases. He served as president of the Philadelphia Psychiatric Society in 1909-1910 and of the American Neurological Society in 1908. At this meeting of the society a bronze tablet bearing the names of three benefactors of the county society was unveiled. They are Drs Isidor P. Strittmatter, donor of the award, Dr James M. Anders, founder of the library, and the late Dr Lawrence Webster Fox, who contributed to the support of the society. Dr Joshua E. Sweet, New York, delivered the fifth annual John Chalmers Da Costa Oration on this occasion.

SOUTH CAROLINA

Society Receives Old Souvenir—Col Aiken Simons, Charleston, recently presented to the Medical Society of South Carolina a gold medal given to his father, the late Dr Thomas Grange Simons, in recognition of his work during a yellow fever epidemic in Memphis in 1876. Physicians working in the epidemic organized themselves into a corps known as the Howard Medical Corps, in the name of which the medal was given to Dr Simons. Dr Simons was president of the Medical Association of South Carolina 1888-1889, and during the two following years was president of the Medical College of the State of South Carolina, according to a newspaper account.

TENNESSEE

State Medical Election—Dr John B. Steele, Chattanooga, was elected president of the Tennessee State Medical Association at the annual meeting in Nashville, April 11, succeeding Dr John Owsley Mamer, Nashville. Vice presidents elected were Drs J. Wallace Wilkes, Columbia, Nicholas S. Walker, Dyersburg, and Charles R. Thomas, Chattanooga.

Society News—Dr Thomas D. Moore presented a paper on "Conservation of Renal Tissue" and Drs James R. Reinberger and Percy B. Russell, Jr., Value and Limitations of the Roentgen Ray" before the Memphis and Shelby County Medical Society, March 5.—Drs Fred L. Moore, Blountville, and Edmund A. Lodge, Johnson City, addressed the Washington County Medical Society, April 4, on "Typhoid Control in East Tennessee" and "Medical and Surgical Treatment of Otitis Media, Mastoiditis and Their Complications" respectively.—Drs Henry A. Callaway, Marville, and James W. Norton Walland, addressed the Blount County Medical Society,

May 2 on "Risk of Carcinoma of the Cervix Following Supravaginal Amputation" and Treatment of Influenza," respectively—Dr James G Eblen, Knoxville, addressed the Knox County Medical Society, March 5, on "The Abdominal Pain of Throat Infections and Appendicitis in Children"—Dr John H Tilley, Lawrenceburg, among others, discussed "Treatment of Compound Injuries" at a meeting of the Hardin, Lawrence, Lewis, Perry and Wayne Counties Medical Society, Holtenwald, March 26—A symposium on tuberculosis was presented at a meeting of the Chattanooga and Hamilton County Medical Society at Pine Breeze Sanatorium April 25 with the following speakers: Drs Tolbert C Crowell, William D Anderson, James L Hamilton, Franklin B Bogart, Eugene A Gilbert, John A Steward and Robert C Robertson.

TEXAS

State Medical Meeting at Dallas—The sixty-ninth annual meeting of the Texas State Medical Association will be held in Dallas, May 14-16, under the presidency of Dr Samuel F Thompson, Kerrville. Three general sessions will be held at the Baker Hotel at which the following guests will speak:

Dr Joseph L Miller, Chicago, Recent Advances in Our Knowledge of the Thyroid Gland
Dr Dean D Lewis, Baltimore, Cystic Mastitis
Dr Horton R Casparis, Nashville, Tenn., Allergy in Children
Dr Edward Jacy King, New Orleans, Puerperal Tetanus
Dr Arthur U Deyardins, Rochester, Minn., Radiotherapy for Acute and Chronic Inflammatory Conditions
Dr Morris Fishbein, Chicago, Medicine in the Changing Social Order
Dr Albert C Broders, Rochester, Minn., Cancer as We Comprehend It

Several of the guest speakers mentioned will also address section meetings and in addition Dr Stanley J Seeger, Milwaukee, will present a paper before the section on surgery on the treatment of burns. Dr Austin A Hyden, Chicago, secretary, Board of Trustees, American Medical Association, will show at a meeting of the house of delegates a motion picture presenting activities at the headquarters of the Association. There will be symposiums on disorders of the heart, cancer of the uterus, modern indications for therapeutic abortion, tuberculosis, syphilis and communicable disease control and prevention. The following special organizations will hold their meetings during the week: Texas Railway Surgeons' Association, Texas Radiological Society, Texas Neurological Society, Texas Dermatological Society, Texas Society of Gastro-Enterologists, Texas State Heart Association and Conference of County and City Health Officers.

UTAH

Survey of Medical Facilities—The committee on economics of the Utah State Medical Association has completed a preliminary report on medical service and medical facilities in the state. Geographic and population features create problems in Utah that are met in few other states. Only six states have a population density lower than that of Utah: 6.2 persons per square mile, the most thickly populated county has a density of 256, but nineteen counties have population densities of less than five. The average population per physician for the state is 980, but in the counties the number of persons per physician varies from 719 in Salt Lake County to 2,754 in Duchesne. In Daggett County, which is isolated by mountains and forests, there is no physician. In October 1934 there were registered with the state board of registration 594 physicians, 430 dentists, 1,012 graduate nurses, 35 midwives, 18 chiropractors, 92 optometrists, 27 osteopaths, 64 chiropractors, 15 naturopaths and 462 pharmacists. The committee based its report on questionnaires filled out by 470 physicians giving their type of practice, charges, income, expense, training, years of practice, hours of work, persons served, preventive services given and charity work. It was found that 18 per cent of the physicians were specialists and 21 per cent partial specialists, nearly all concentrated in Salt Lake City. Contrary to experience in other parts of the country, it was found that younger physicians tended to settle outside the larger cities. Thirty per cent of those who replied reported that they held either part time or full time salaried positions, and 17 per cent more reported that all or most of their work was on a specified fee basis. Concerning individual incomes it was found that 23.6 per cent of the physicians in Utah had net incomes under \$2,000 in 1933 and 61.1 under \$3,000. The average number of hours worked per week was 63.7 hours; one physician reported working 104 hours per week and the report interpolates that he suffered a breakdown from heart disease at an unduly early age. Many reported that they had taken no vacations in 1933. Thirty-six hospitals have 3,037 beds, 42 per cent of which are in Utah County, where there are two mental hospitals. Fourteen counties have no hospitals. Nearly one fifth of the physicians replying to the questionnaire expressed dissatisfaction with the hospital facilities available to them. The state has a well

organized department of health, but its funds are seriously restricted. County health departments are practically nonexistent. An estimate of the expenditures for the services of physicians in 1933 approximated \$2,887,100, or \$5.50 per capita for the state. The physicians estimated that, in the first three months of 1934, 29 per cent of their work was charity to those unable to pay, in several counties the proportion was as high as 75 and 85 per cent. Counties make little provision for care of the indigent sick and at least six counties make none; it was said. Study of incomes of the population revealed that 25 per cent of the population were unable to pay for medical service and another 35 per cent were able to bear only part of the cost. As a result of study of these and various other factors, the committee outlined specific recommendations for the provision of better medical service, including the establishment of periodic prepayment plans to certain limited groups governed by certain specific principles. The state association was asked to urge governmental units to make better provision for hospital service care of the indigent and extension of public health services. Finally it was proposed that a central office be established with a full time executive secretary.

WEST VIRGINIA

State Medical Meeting at Wheeling—The sixty-eighth annual meeting of the West Virginia State Medical Association will be held in Wheeling, May 6-8, with headquarters at the Hotel McLure and under the presidency of Dr Rome H. Walker, Charleston. Section meetings will be held the first day. In cooperation with the West Virginia Heart Association the section on internal medicine will have the following guest speakers:

Dr George W Crile, Cleveland, Surgical Treatment of Diseases of the Cardiovascular System, Problems in the Diagnosis and Treatment of the Thyroid, Adrenal, Sympathetic System
Dr Russell J Cecil, New York, Recent Conceptions in the Therapy of Pneumonia, Bacterial Endocarditis
Dr Thomas R Brown, Baltimore, Peptic Ulcer with Particular Reference to Differential Diagnosis and Treatment

Dr Howard L Stitt, Cincinnati, will address the eye, ear, nose and throat section on Bronchial Suppuration of Non-tuberculous Origin and Treatment by Bronchoscopy and Bronchial Lavage and Dr Stewart H Clifford, Boston, the section on pediatrics, on "Reduction of the Premature Infant Mortality." The program of the general sessions includes the following addresses:

Dr Morris I Wendeloff, Charleston, Management of the Psychoneurotic by the General Practitioner (the oration in medicine)
Dr Benjamin O Robinson, Parkersburg, Some High Points in Surgical Progress (the oration in surgery)
Dr Morris Fishbein, Chicago, editor of THE JOURNAL, The Work of the American Medical Association (motion pictures)
Dr Elmer Hess, Erie, Pa., Relationship Between Urinary Pathology and Abdominal Symptomatology
Dr Clifford, Determination of Fetal Size in Utero by Stereocentrometry
Dr John E Brown, Sr, Columbus, Ohio, Evolution of Otolaryngology as a Medical Specialty
Dr Virgil E Simpson, Louisville, Ky., Jaundice as a Clinical Phenomenon
Dr Irvin Abell, Louisville, Uterine Hemorrhage

Dr Fishbein will also make an address at the annual banquet at the Fort Henry Club, Wednesday evening, May 8, on "Our Changing Times." Dr Walker will make his presidential address Tuesday evening on "Personal Observations on Medical Practice in West Virginia."

WISCONSIN

Bills Introduced—A 758 proposes that whenever it is relevant in a bastardy proceeding the trial court may order the prosecuting witness, her child and the defendant to submit to one or more blood tests to determine whether or not the defendant can be excluded as being the father of the child. The bill further proposes that whenever it is relevant in a civil action to determine the parentage or identity of any child, person or corpse, a court may direct any party to the action to submit to one or more blood tests. A 765 proposes to prohibit persons, associations or corporations, other than licensed physicians, to make any report to or for any insurance company regarding an applicant for life, accident or health insurance without a license from the commissioner of insurance. A 733 proposes to authorize the State Medical Society of Wisconsin, or any county medical society, to undertake and coordinate all sickness care of indigents and low income groups through contracts with public officials and with physicians and others, and by the use of contributions, cooperative funds and other means provided only that free choice of physician without such contracts shall be retained and that responsibility of physician to patient and all other contract and tort relationships with patient shall remain as though the dealings were direct between physician and patient.

GENERAL

Teachers for Sight-Saving Classes—Courses for the training of teachers and supervisors of sight-saving classes will be offered this summer at the following schools: Western Reserve University, Cleveland, June 24-August 2; State Teachers College, Buffalo, July 1-August 9, and Teachers College, Columbia University, July 8-August 16. Information may be obtained from the schools or from the National Society for the Prevention of Blindness, 50 West Fiftyeth Street, New York.

Bequests and Donations—The following bequests and donations have recently been announced:

Mount Sinai Hospital, New York and Stony Wold Sanatorium \$25,000 each by the will of the late Dr. Benjamin Stern
Beekman Street and St. Vincent's hospitals \$500,000 New York Foundling Hospital \$50,000 and Beth Israel Hospital \$200,000 all of New York by the will of the late Conrad Hubert

Pittsburgh Eye and Ear Hospital \$50,000 and Trudeau Sanatorium Trudeau N. Y. \$25,000 from the estate of the late Elizabeth W. Childs, Pittsburgh, following the death of a relative who is the immediate beneficiary. The remainder of her \$150,000 estate is to be held in trust for the Tuberculosis League of Pittsburgh.

Sydenham Hospital, New York \$3,000 from the estate of the late Cornelius Houbt.

University of Cincinnati, \$12,500 as a gift from Mrs. David May to establish the David May fund in internal medicine in the college of medicine.

Jefferson Medical College Philadelphia \$250,000 by the will of the late Alva B. Johnson who was chairman of the board of trustees for many years.

Southeastern Surgeons' Meeting—Dr. Charles Jefferson Miller, New Orleans, was chosen president-elect of the Southeastern Surgical Congress at its annual meeting in Jacksonville Fla., March 11-13 and Dr. William D. Haggard, Nashville, Tenn., was installed as president. Dr. Carl C. Howard, Glasgow, Ky., was made vice president, and Dr. Benjamin T. Beasley, Atlanta, reelected secretary. The next session will be in New Orleans. Among speakers at the meeting were:

Dr. Chevalier Jackson Philadelphia Asphyxia Methods for Its Prevention

Dr. George W. Crile Cleveland Technique and End Results of the Surgical Treatment of Diabetes and of Polyglandular Disease

Dr. Hugh Cabot Rochester Minn. Management of the Incompletely Descended Testicle

Dr. Walter C. Alvarez Rochester Minn. Helpful Hints for Picking Out the Patient Who Would Be Worse After Operation

Dr. Arthur E. Hertzler, Halstead Kan. Predicting the Type of Peritonitis That Will Develop from a Given Case of Appendicitis

Dr. John F. Erdmann New York Injuries to the Common Duct with Consideration of Methods of Repair

Medical Bills in Congress—Changes in Status S. 2214 has passed the Senate, conferring jurisdiction on the United States district courts over Osage Indian drug and liquor addicts. **Bills Introduced** H. J. Res. 248, introduced by Representative Gasque, South Carolina, proposes to create a United States Food Research Commission to carry into effect such studies as are necessary in order to determine the food values of the various articles used as foods in the several sections of the United States. H. R. 7684, introduced by Representative Terry, Arkansas, proposes to erect an addition to the existing Veterans' Administration facility at North Little Rock, Ark. H. R. 7485, introduced by Representative Johnson, Oklahoma, proposes to increase the efficiency of the Medical Department of the Regular Army by creating a Medical Administrative Corps. H. R. 7629 introduced by Representative Brooks, Pennsylvania, proposes to erect an addition to the existing Veterans' Administration facility at Aspinwall, Pa. H. R. 7651, introduced by Representative Kimball, Michigan, proposes to authorize the erection of an addition to the Veterans' Administration facility at Camp Custer, Mich. H. R. 7679, introduced by Representative Koppelman, Connecticut, proposes to authorize the erection of an addition to the existing Veterans' Administration facility at Newington, Conn. H. R. 7691, introduced by Representative Greever, Wyoming, proposes to authorize the erection of an addition to the existing Veterans' Administration facility at Cheyenne, Wyo. H. R. 7710 introduced by Representative Sanders, Louisiana, proposes to compensate those persons afflicted with leprosy who are patients isolated in the United States Marine Hospital at Carville, La. H. R. 7735 introduced by Representative Green, Florida, proposes to authorize the erection of an addition to the existing Veterans' Administration facility at Lake City, Fla.

Society News—The American Association for Thoracic Surgery will hold its eighteenth annual meeting in New York, June 3-5. Among speakers listed on a tentative program are Drs. Henry Norman Bethune, Montreal on Operative Methods of Closure of Bronchopleural Pleurocutaneous and Bronchocutaneous Fistulas; William P. Herbert, Asheville, N. C. Tuberculous Empyema; Armistead C. Crump and Haig H. Kasabach, New York Treatment of Carcinoma of the Esophagus by Combined X-Ray and Radium; Richard H. Overholt, Boston Pneumonecomy for Carcinoma and Pulmonary Sup-

puration," and Edward J. O'Brien, Detroit The Choice of Procedure"—The American Society of Clinical Laboratory Technicians will hold its third annual meeting at Haddon Hall, Atlantic City, N. J., June 10-12.—The American Association of Medical Milk Commissions will hold its annual meeting in Atlantic City, N. J. June 10-11.—The American Orthopaedic Association will hold its forty-ninth annual meeting in Philadelphia June 5-8 under the presidency of Dr. DeForest P. Willard, Philadelphia. The program includes two symposiums: one on arthritis will be presented by Drs. Walter Bauer, Robert B. Osgood and Loring T. Swaim, Boston, Ralph Pemberton Philadelphia; Joseph A. Freiberg, Cincinnati, and Robert W. Johnson, Baltimore. A fracture symposium will be given by Drs. Hiram Winnett Orr and James E. M. Thomson, Lincoln Neb.; Robert D. Schrock, Omaha; James S. Speed, Memphis Tenn.; Robert V. Funsten, University, Va., and Kellogg Speed, Chicago.—The annual Alpha Omega Alpha dinner will be held during the annual session of the American Medical Association at the Hotel Ambassador, Atlantic City, N. J. Thursday evening, June 13, at \$2 per plate.—The alumni dinner of Rush Medical College (University of Chicago) will be held during the annual session of the American Medical Association at the Hotel Ambassador, Wednesday evening, June 12, at \$2 per plate.—Dr. Simeon Burt Wolbach, Boston, was elected president of the American Association of Pathologists and Bacteriologists at the annual meeting in New York, April 19, and Dr. Howard T. Karsner, Cleveland, secretary. Next year's meeting will be held in Boston.—Frank R. Lillie, Ph.D., dean of the division of biological sciences, University of Chicago, was elected president of the National Academy of Sciences at the annual session in Washington, D. C., April 24.—The Academy of Physical Medicine will hold its annual meeting in Atlantic City, June 12-13, at the Hotel Claridge.

Government Services

Rural Health Service

Seventy-three per cent of the rural population in the United States is still without the form of health organization that is considered best adapted to rural areas, according to *Public Health Reports* in a review of rural health service for 1933. During this year there were fifty-five full time health units discontinued and only four established, giving a net loss of fifty-one units. Virginia suffered the greatest loss with the discontinuance of full time health work in nine counties, while Delaware led in the percentage of rural population under full time health service, all of its three counties having been provided with local full time health organization by the state. Of the states in which the local governmental units maintain the health organizations, with or without assistance from the state health department or other sources, Maryland had the highest percentage (97.5) of rural population under full time health service. Of the 530 counties, townships or districts with health service under local full time health officers, 491, or 92.6 per cent, were receiving financial assistance for the support of their health service from one or more of the following agencies: the state board of health, the U. S. Public Health Service, the Rockefeller Foundation, the American Red Cross, the American Women's Hospital Fund, the Rosenwald Fund, the Commonwealth Fund and the Milbank Memorial Fund.

Vender of Cancer Cure Dies of Cancer

The U. S. Department of Agriculture announced that the government's case against Charles W. Mixer, self-styled cancer specialist of Hastings, Mich., on a charge of violating the federal food and drugs act, had been dismissed because of the defendant's death from cancer. Even during Mixer's last illness, his office force continued to sell his so called cancer cure.

Examination for Appointments in the Navy

An examination of candidates for appointment in the Medical Corps of the U. S. Navy will be held at the Naval Medical School, Washington, D. C. and at the Naval Hospital, Mare Island, San Francisco, June 10. Candidates must be between 21 and 32 years old. They must also be graduates of schools listed as class A by the Council on Medical Education and Hospitals of the American Medical Association and must have completed a general internship of at least one year in a hospital accredited for internship by the American Medical Association. For further information address the Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

The Struggle of the Osteopaths for Registration

At the inquiry on the osteopaths' bill in the house of lords, Sir William Jowitt, attorney for the British Medical Association, who addressed the committee, said that the number of persons in this country calling themselves osteopaths was estimated at between 2,000 and 3,000. Among them were 179 who claimed to be 'qualified' of whom some ninety-six had gone through the British School of Osteopathy and the other eighty-three had some American qualification and of these about half were Americans. According to Dr. Macdonald (the physician who practices osteopathy and gave evidence reported previously in THE JOURNAL) there was no reputable school of osteopathy in this country and therefore none fit to be recognized by the state. No osteopath who treated acute diseases had been called before the committee, and there was no evidence that any osteopath in England did. The function of education was to enable the student to think for himself, and it was a mistake to start him from a prejudiced point of view by telling him that he was never to use drugs. The right solution was to let students take their degrees and then work in any way they liked. The bill would do a grave public injury by duplicating machinery and setting up a second register.

Sir Henry Brackenbury, vice president of the British Medical Association and a member of the General Medical Council, said that there was now a movement by the council to place the whole of general biology in the premedical stage, so that the five years medical education would begin after the student had taken this, with physics and chemistry. The osteopaths' point of view was not whether a patient had bronchitis or pneumonia or gallstones but whether the basic cause of his disease was in the second or the seventh cervical vertebra. The doctor's diagnosis might or might not have something to do with the spinal column, but it was directed to form a picture as exact as possible of what was going on in the patient's body. To pick out a particular cult for registration would give a cachet of authority to theories unacceptable to almost the whole scientific world. It seemed to him inconceivable that the anatomists and physiologists who for 100 years have been investigating the structural and functional states of the body should have failed to observe the osteopathic lesion.

Sir Edward Sharpey-Schafer

Sir Edward Sharpey-Schafer, F.R.S., emeritus professor of physiology in the University of Edinburgh, has died in his eighty-fifth year. Born in London, he was educated at University College Hospital, where he was a pupil of the great anatomist and physiologist William Sharpey. In 1874 he became assistant professor of physiology to Burdon Sanderson, another great physiologist, who had succeeded Sharpey in the chair. In 1883 he became professor of physiology at University College and in 1899 at Edinburgh. He was invited to lecture at Johns Hopkins University and at Stanford University. His earlier work was mainly histologic. That on the structure of striped muscle, in which he used the wing muscle of insects to illustrate his view, has become classic. With Horsley he made some of the earlier researches on cerebral localization. With Oliver he showed the effects produced by intravenous injection of extracts of the adrenal medulla which led to the discovery of epinephrine and other hormones. Twenty-three years ago, in a remarkable presidential address to the British Association he maintained that life was no 'mysterious force' but was due to the action of physicochemical laws. He is best known to

the general public by his manual prone pressure method of artificial respiration. The physiologist Sir Leonard Hill in a tribute to him recently said that his contributions to physiologic science are stored in the libraries and utilized daily by research workers in extending frontiers that he did so much to advance. His most important books were "Essentials of Histology" and "The Endocrine Organs." He edited an "Advanced Textbook of Physiology," to which leading physiologists contributed. He started and edited, up to his retirement, the *Quarterly Journal of Experimental Physiology*.

Gas Dangers in Air Raids

In a lecture at the London headquarters of the British Red Cross Society, Major H. S. Blackmore, an expert on poison gas, said that the society was training a large body of voluntary workers to protect and aid the civil population in the event of war from the air. The safest shelter in the event of an air raid was an ordinary room rendered gas proof, on or about the first floor. People who rushed into underground tubes or dugouts would not be so safe as those who went quietly upstairs to the antigas sitting rooms, where they would remain until all danger was past. In the air raids there would be two distinct dangers—death or injury from high explosives and from gas. People who rushed underground to avoid explosive bombs would not be safe from gas, which was so heavy that it sank rapidly. A heavy cloud of poison gas tended to disperse 20 feet above the level of the ground. Danger from gas might still be present hours after an attack. Most rooms could be made gas proof by sticking brown paper round the cracks of doors and windows and over the entrance to chimneys. Two wet blankets could be hung over the entrance door, one on the inside and one on the outside.

The Red Cross is concentrating on training a large body of voluntary workers to cope with an emergency. Antigas drill is divided into three parts. 1. Workers in the streets will control crowds and deal with street casualties. 2. There will be Red Cross first aid stations and hospitals. 3. Decontamination brigades will clear away the gas from danger areas and decontaminate the clothes of casualties. It is held that every physician in the country should be trained to deal with gas casualties.

The Methods of a Medical Trade Union

In previous letters the Medical Practitioners Union, a body consisting of more than 5,000 physicians working on trade union lines, has been described. A question asked in parliament shows something of the methods adopted by the union. It appears that it is circularizing local authorities (some of which are under the control of socialist majorities and therefore likely to be sympathetic to it) requesting them to consider the recognition of the union and the insertion of advertisements for vacant medical appointments in its official weekly organ, called the *Medical World*. Sir Hilton Young, minister of health, replied that the law forbade any local or public authority to make it a condition of employment of any person that he should, or should not, be a member of a trade union.

Damages for Negligence Against an Osteopath

It is unfortunate for the osteopaths that, just at the time when they are attempting to convince parliament that they are worthy of recognition, heavy damages for negligence should be awarded against a well known osteopath, Captain Lowry, who lost his sight at the battle of Neuve Chapelle. He qualified as a masseur from St. Dunstan's (the institution established for the training of blinded soldiers) and he has practiced as an osteopath since 1925. A girl was taken to him for rheumatism. He scouted the diagnosis and said that she had a twisted intestine and a slight dislocation of the left hip. He manipulated the joint under an anesthetic and she was taken home in great

pain. She was found to be suffering from fracture of the neck of the femur, which was platted by a surgeon. Captain Lowry denied that anything untoward happened when he was manipulating the patient's limb or that he used violence. In his evidence he claimed great delicacy in his sense of touch, which he demonstrated by telling what card of a pack was placed in his hand by passing his fingers over the face. While the judge expressed admiration for his courage and success in taking up a new career after he had lost his sight in his country's service, the jury awarded \$7,500 damages to the girl.

March 29 1935

Proposed Changes in Social Insurance Law

In a recent letter, mention was made of a deficit in the budget of the social insurance law. An effort is being made to correct the abuses and deficit in the form of a law submitted February 27 by Senator Edmond Cavillon, supported by 184 of his colleagues, which number constitutes a majority of the French senate.

The arguments in favor of changing the law are as follows. The economic crisis has begun to involve France, in spite of continued resistance to its effects. It has become imperative to reduce government expenditures to the minimum. This is especially applicable to the social insurance law, which since its introduction in 1930, has aroused much justified criticism and an unexpected lack of success. It is not the intention of the legislature to annul the law, which is based on the highest motives toward the amelioration of social conditions. Several efforts to annul the law or suspend it temporarily have been defeated. This would signify that, in principle, there is no opposition to such a law. Such an agreement as to the aims of social insurance, however, must not permit a government to omit every effort to simplify the law and to reduce the complicated machinery that has been necessary in carrying it out. Above all, it has become imperative to lighten the burden of expenditures, which the deficit in the budget of social insurance has compelled the government to pay. To recognize the fact that one has been wrong is not an evidence of weakness' is a quotation from an article by Milan in the *Revue politique et parlementaire* written in 1933 who is quoted further as saying "The law is badly thought out. Let us have the courage to recognize this and correct its faults."

Public opinion has demanded changes in the law but only a few absolutely necessary ones have been made. The law is obligatory, but the question has arisen as to whether this principle of obligation is being respected. Even the government does not compel its employees to be insured. More than ten million people are subject to the law, but only five million industrial and 640,000 out of 1,000,000 of those in agricultural pursuits are paying their premiums. Whether respected or not the social insurance law has had some important financial consequences. From July 1 1930, to Oct. 31, 1934, the figures are as follows:

Premiums received from employers and employees	14 050 000 000 francs
Additional expenditure by the government in the form of subsidies and supplementary credits	3 500 000 000 francs

This is a burden for the government that cannot be well tolerated during the present economic crisis.

The outlay on the part of the government for the administration of the law alone (included in the figures) amounts to more than 100 million francs (six and a half million dollars). This figure corresponds only to a part of the outlay for social insurance. One must add an equal amount for the expenses of carrying out the law by the caisses or bureaus of collection and distribution of the premiums and benefits. In spite of every

effort to economize, the various offices in charge of the administration of the law complain of not having enough personnel.

A glaring defect in the law is that relating to old age insurance. The idea of the legislator was to permit a large number of older workers to retire and thus create jobs for younger persons. A large number of workers who were more than 65 years old when the law went into effect in July 1930 have been excluded from the benefits of the law and are not eligible for old age pensions.

The 185 senators who signed the petition to change the law conclude as follows:

"After so many demands for reform in the social insurance law we also add ours to change a law that has not been satisfactory to employers, employees or administrators of the law.

"The principal objective of such a reform is to simplify the law in such a manner as will increase the efficiency and decrease the expenditures.

"The law from a theoretical point of view is good but it should be made simpler, more practical, more humane and less costly."

Students Appear Before Committee of Legislature

Representatives of the national and local student organizations presented their side of the agitation against foreign physicians, February 13, before the committee on hygiene of the chamber of deputies. The student organizations demanded the following:

Only French students who have completed their required courses and are eligible for state diplomas can act as substitutes for physicians. Such substitution shall be legalized by the local authorities. More careful investigation of the records of those who apply for naturalization shall be made by the police. The faculties of the medical schools have not been strict enough in accepting equivalents for the bachelor of arts degree, which is necessary for admission. No one shall be permitted to change the 'university diploma,' which does not entitle its holder to practice in France or its colonies, into a "state diploma," which does bestow the right to practice. No one shall be allowed to practice here unless naturalized ten years before graduation. Military service shall be obligatory for all such individuals.

One Hundredth Anniversary of Death of Dupuytren

Exercises will be held April 7, in memory of the French surgeon Dupuytren. He died Feb 7, 1835. Professors Cuneo and Carnot will preside at the meeting which will be held at the Hotel-Dieu, one of the oldest hospitals and the one in which the famous surgeon worked.

The Franco-Mussulman Hospital in Paris

There are at present in Paris 50,000 natives of the French colonies, especially those in northern Africa. The government therefore decided to construct a hospital so as to give these natives the benefits of modern medicine and at the same time conform to their habits and religion. The new hospital, opened March 22, is situated in one of the suburbs of Paris. The surgical service is in charge of Dr. Maurice Thalheimer, an assistant of Professor Gosset and well qualified to fill the position.

French Gynecologic Congress

This year's French Gynecologic Congress will be held June 8-10 at Salles-de-Bearn, a watering place specializing in gynecologic ailments. The honorary president is Dr. Doleris and the president is Professor Guyot of Bordeaux. The chief subject to be discussed is Genital hemorrhages excluding those due to pregnancy and tumors. The papers include those on the anatomy of the female genital tract, hemorrhages due to systemic and local causes and medical, physical therapeutic and surgical treatment of genital hemorrhages.

Disability Insurance in 1933

The president of the Reichs Versicherungsamt has just published a report dealing with disability insurance for the year 1933. Disability insurance is quite distinct from the ordinary health insurance, it provides insurance for invalids and the aged and the insured members have usually paid their premiums over a long period. As the president Dr. Schäffer, stated, the position of this insurance in the beginning of 1933 was very discouraging. By reason of the constantly diminishing receipts the fulfilment of the legal obligations encountered difficulties, so that assets of the disability insurance had to be liquidated at a heavy loss. The total expenditures for the application of the various therapeutic procedures and for cash benefits had to be restricted to 40,000,000 marks (\$16,000,000). Including the supplementary performances the carriers of disability insurance received in 1933 approximately 41,500,000 marks for the promotion of health, as compared with 51,500,000 marks in 1932. Actual therapeutic measures required the expenditure of about 29,000,000 marks, general measures 9,700,000 marks and care of orphans 155,000 marks while miscellaneous expenditures amounted to 2,600,000 marks. The report contains this statement: To what extent this enforced limitation of the therapeutic procedures will result in an exacerbation of health conditions among the insured members and in an increase of cases of disability cannot be determined as yet. The expenditure of the 29,000,000 marks sufficed to provide adequate and complete treatment for 89,118 persons affected with various diseases, 24,815 with tuberculosis (including lupus), 9,109 with venereal disorders and about 55,000 with other disorders which included some 21,000 with dental disease. Disorders affecting the nerves, the heart, the vascular system and

Average Expenditures for Patients in 1932 and in 1933

Type of Disease	Cost per Case in 1932 Marks	Cost per Case in 1933 Marks
Pulmonary and laryngeal tuberculosis	874.37	1,202
Tuberculosis of bones and joints	1,286.30	1,069.76
Lupus	724.20	463.69
Venereal diseases	224.38	160.14
Rheumatism	347.74	311.30
Cancer	210.57	253.65
Other diseases	351.11	304.08

the digestive organs were much in evidence. The average expenditure for a patient with pulmonary or laryngeal tuberculosis was 753 marks, in the other diseases about 300 marks. As compared with 1932, the average expenditures were much lower, as may be seen from the table.

It is interesting that, of 121,798 patients supposedly with venereal disease, only about half (63,887) were actually affected. More than 40,000 presented themselves voluntarily for examination, which speaks well for the functioning of the consultation centers. Aside from the actual therapeutic procedures, the general measures for the prevention of premature disability among the insured or for the improvement of their health constitute an important field of endeavor, which includes the creation and support of therapeutic centers, welfare aid centers and the extension of welfare aid for therapeutic purposes to the uninsured or underinsured juveniles and to mothers with a large number of children. For these purposes nearly 10,000,000 marks was supplied in 1933 (11,700,000 marks in 1932). It was regrettable that retrenchment was necessary in the matter of welfare aid for children, only about 3,000,000 marks was available for this purpose. Finally, the health mea-

sures of disability insurance, included the granting of loans for public enterprises, for example, for the improvement of the bad housing situation or for the creation of healthy dwellings to lessen the dangers of infection. In the main, funds for the erection of small, moderately priced dwellings are lent to building and loan associations. Up to the end of 1933 a total of 337,700,000 marks (\$135,000,000) had been lent for such purposes. Also for the promotion of the general welfare, namely, for the construction of hospitals and homes for convalescents, therapeutic centers for persons of moderate means, homes for invalids, bath establishments for the masses, water systems, and the like, the carriers of disability insurance have always furnished funds, as far as they were able, the total of such expenditures amounting up to the end of 1933 to 560,000,000 marks (\$224,000,000).

The Typhoid Epidemic in Children

Of 187 cases of typhoid that were treated in Königsberg, fifty occurred in children. Of this number, forty-one were treated in the Municipal Hospital. At a meeting of the Königsberg Medical Society, Dr. Rau discussed this series of cases. The number of cases of typhoid in children, as compared with the number of adults affected, was small, although the milk used was the apparent cause. This fact seems at first hard to understand, since young persons commonly drink much more milk than adults. These forty-one patients belonged to forty families with a total of ninety-three children. It appears therefore that in fifty-two children who likewise drank infected milk no infection developed. The course of the disease in these children was rather severe, whereas typhoid in children generally takes a mild course. Nine children were entirely unconscious for some time. High temperatures lasted, without complications, from six to eight weeks. The usual blood picture with leukopenia and aneosinophilia, was present in only a little better than half the patients (57 per cent). Hemorrhages, otitis purulenta and peritonitis occurred in only three cases. Only one case ended fatally. As a special therapeutic measure the children were given an ample mixed diet, to preserve their strength as long as possible. On the appearance of diarrhea, they were given crushed banana or crushed raw apple, together with the application of the usual measures. The results were good. Perforation of the intestine did not occur in a single case. There were, however, relapses in fifteen cases.

In the Rostock University Children's Clinic, according to the statements of Dr. Erben, the systematic application of the Widal test to all new entrants among the children made it possible to diagnose many cases of apparently nonspecific influenza like infections and intestinal catarrh as typhoid. But only an agglutination titer of at least 1:400 was found to be pathognomonic.

The Probability of Multiple Births

A compilation of the multiple births occurring in Germany in the years 1901-1925 shows that, of the 42,107,657 births recorded in this period 531,541 were twin, 5,364 were triplet, and sixty-seven were quadruplet births. One group of quintuplets was born. In general, it is figured that one twin is born out of eighty children, one triplet out of about 6,400 and one quadruplet out of 500,000. A quintuplet birth occurs only once in fifty million births. With the exception of the recent report of the quintuplets in Canada, there are no reasonably authentic reports of quintuplets who all survived for any considerable time. The probability of multiple births can be reduced to a mathematical formula. The number of births to be expected may be expressed by the formula $1/n^{x-1}$, n being the number of single births that occur in a given country in relation to a twin birth, while x shows the nature of the multiple birth (twins, triplets, quadruplets). For example, in Ger-

many n^{x-1} for triplets $\approx 80^{3-1} = 80^2 = 6,400$ In determining the number of quadruplets $n^{x-1} = 80^3 = 512,000$ In ascertaining the relation of the number of quintuplets to the total number of births the formula $1/n^{x-1} = 1/80^4 = 1/40,960,000$ One obtains accordingly with these formulas figures that correspond to the actual conditions According to this formula, sextuplets might be expected once in three billion births

Prof Walter Spielmeyer

Prof Dr Walter Spielmeyer director of the Bram Institute of the Deutsche Forschungsanstalt für Psychiatrie in Munich died, February 6 at the age of 55 Spielmeyer carried further the work of the school of Nissl and von Alzheimer and during the past twenty years had been the unquestioned leader in anatomy of the brain He was regarded as the leading authority with respect to the only histologically recognizable anatomic changes in mental diseases infections and intoxications of the brain, the nervous system the medulla oblongata and the spinal cord His most important researches dealt with the changes due to paralysis He succeeded in helping to establish a pathologic anatomy of the psychoses a science that is already out of its infancy Many years elapsed before this branch of research gained recognition philosophical opinions were however, advanced to the effect that disorders of the intellect mind and psyche should be considered in the same manner as the disorders of the body He was able to complete the first volume of his textbook on the histopathology of the nervous system

Feb 15 1935

Congress of the Neurosurgical Society

The Società radio-neuro chirurgica held recently its national congress in Milan, under the presidency of Professor Donati The chief topic on the program was 'Research Criteria in Disorders of the Nervous System'

Professor Boschi dealt with the diagnosis of endocranial tumors

Professor Bertolotti the speaker on the radiologic side of the subject, based his presentation on his personal experience with a large series of cases Speaking of the ventricular system and of the subarachnoid spaces he stated that Dandy was able to demonstrate in experiments on internal hydrocephalus, that when there is an obstruction along the circulatory path of the cerebrospinal fluid the part of the system that lies above the obstruction becomes dilated This fundamental observation led Dandy to the discovery of two methods of gas insufflation spinal encephalography and direct ventriculography With regard to the technic of spinal encephalography the speaker holds that it should always be total and hence is not adapted to small insufflations One cannot however hope to procure the visualization of all the windings through which the cerebrospinal fluid circulates It is necessary to repeat the radiographic tests at intervals during the first twenty-four hours the stereoscopic examination is likewise valuable Encephalography is particularly useful in determining the effects of crano-encephalic traumas in which the phenomenon of the migratory ventricle and that of the unilateral internal hydrocephalus may be seen In case of tumors and when there are clinical symptoms of hypertension, the speaker thinks it is more advantageous to apply direct puncture of the ventricles In cases of jacksonian epilepsy encephalography is still the only means of reaching an early diagnosis of cerebral tumor It constitutes a valuable means of research also in the study of essential epilepsy The use of opaque substances such as iodized oil and thorium dioxide sol may give good results but their harmlessness has not yet been demonstrated The author concluded that collective

experience shows that the symptomatology of cerebral tumors is insufficient to establish an exact topographic diagnosis

Prof Raffaele Bastianelli, senator, to whom was assigned the surgical presentation, emphasized that, in disorders of the nervous system, examination of the spinal fluid is highly important The fluid may be taken from the cisterna or through lumbar puncture, but only ventricular puncture, with visualization of the ventricles, enables one to ascertain accurately the condition of the brain To study exactly the conditions in the ventricles it is advisable to make a bilateral puncture at symmetrical points For the occipital puncture the speaker recommended the prone position

The average capacity of the ventricles is 25 cc, as measured by aspirated extractions The interventricular communication is revealed by injecting 2 cc. of indigo carmine into one of the ventricles and observing whether the colored fluid emerges on the other side In applying ventriculography a certain quantity of fluid is extracted and an equal quantity of air is slowly injected This is reabsorbed within three to five hours by the subarachnoid space, and after six to ten hours by the ventricles If the ventricular system is obstructed, the reabsorption of the air may possibly require several weeks

The injection of the air produces irritation of the ependyma and hence hypersecretion of the cerebrospinal fluid and increase of the intraventricular pressure Headache nausea and an increase of temperature of from 1 to 2 degrees occur A drowsy state is cause for alarm In case of tumors with hypertension and hydrocephalus the injection of air is dangerous But the observations of ventriculography are not probative unless there is obstruction of the downward flow of the cerebrospinal fluid or ventricular deformation There are some failures, but they are often the consequence of faulty technic On the whole, it may be said that with this method the possibility of diagnosis is from 70 to 90 per cent in case of tumors Ventriculography is especially indicated if there is an increase of the endocranial pressure for which no cause can be determined If there is no increase of pressure, encephalography is preferable, since the ventricles do not recover so readily and the quantity of air injected is less

Barré of Strasbourg stated that he regarded as true hypertension of the cerebrospinal fluid that which exceeds 50 mm of water in the supine position He explained the syndromes due to the vestibular paths—the cochlear, the pyramidal and the extrapyramidal Mascherpa of Milan spoke on the opaque substances to be used in ventriculography, stating that at present one is confined to the introduction of iodized oil in accordance with the Arce technic

Palmeri of Bologna emphasized that the use of contrast mediums in radiology should not cause ordinary craniography to be discarded The latter, however, gives only indirect signs, which require a more careful interpretation than the direct signs supplied by pneumography

Prof Carlo Lotti

Prof Carlo Lotti, occupant of the chair of special medical pathology at the University of Pisa has died at an early age He was a representative of the Florentine school and had been *aiuto* in clinical medicine under Professor Grocco, and later director of the Antirabic Institute He held then successively a chair in medical pathology at the universities of Sassari, Cagliari and Pisa Among his numerous publications, particular interest attaches to those on peritoneal infection the opsonins and the bacteriotropines, on recurring tuberculous meningitis and on favism Sixty publications by his pupils demonstrate the importance of his work as a teacher He collaborated in the compilation of the Italian Treatise on Internal Medicine, having prepared the chapter pertaining to the diseases of the peritoneum

BELGIUM

March 6, 1935

Government Supervision of Home Work

The government has passed a law providing for the supervision of home work. A commission has been appointed whose duty it will be to decide questions of wages and hygiene pertaining to home workers of both sexes. Within the present law, a home worker is a person performing work either in his own home or in some other place that is not assigned to him by his employer, provided he has no more than four assistants. The assistants of a domiciliary worker benefit from the present law, irrespective of the place in which they are employed. The commission—Comite national pour le travail a domicile—is composed of three industrialists, three workmen, and a person well versed in the economic and social sciences, who will be the chairman. The king chooses the members of the commission—the industrialists and the workmen—from the list of candidates presented by the professional organizations that best represent the employers and the workmen. The Comite national studies questions pertaining to the hygiene of these workers at the request of the communal administrations of the localities in which the workmen are engaged. Its conclusions are communicated to the minister of industry and are submitted by him to the Conseil superieur du travail and to the Conseil superieur de l'hygiene. A royal decree, at the suggestion of the minister of industry will convert, if it seems desirable, these conclusions into compulsory regulations.

A New Physical Education Society

Under the chairmanship of Professor Spehl, the Societe medicale belge d'education physique et de sports has been created. At the opening session, Dr. Brouha pointed out the increasing interest in problems of personal hygiene and the great need of scientifically trained directors. The group of physicians engaged in physical education will have to organize sport on a more scientific basis. The government saw the needs of the situation among the youth in our universities when it created two institutes of physical education at Ghent and at Liege which will be ready to function in 1935. But this action should be extended to all educational institutions, as is being done in central Europe, France and Italy. In any event, the medical control of physical education and of sports should remain in the hands of the physicians. A reform of instruction from this point of view is desirable, notably as regards a diminution of the lecture and recitation hours. It is to be hoped that the society will collaborate with the Commission superieure d'education physique and with similar international societies and participate in the various congresses, at which Belgium has never been represented. Mr. Rene Ledet stated the purposes of the society, which will be chiefly to give proper guidance to the universities, the secondary schools and the societies in establishing relations with the medical societies in foreign countries, to defend the rights and outline the activities of the physicians in the practical organization of sport, and to take an interest in the organization of school programs.

The Crusade Against Quackery

All countries are interested in the efforts being put forth to eradicate quackery, which is developing in all corners of the globe. At the meeting in Madrid of the Union internationale contre le peril venerien, Mr. Schraenen of Brussels presented a paper dealing with the legislative measures of various countries to combat quackery in medicine which is an actual menace and is a hindrance in the crusade against venereal diseases. It is regrettable that some countries ignore officially the crusade

against charlatanry. The lack of interest manifested by certain legislators is due to legal and financial problems or to lack of appreciation of the great need. The forms of medical quackery vary. One type is organized by individuals who are not physicians and who have no professional qualities. Against this type the laws pertaining to the illegal practice of medicine may be invoked. Other types of charlatanry are organized by persons who have had a professional training (pharmacists, for example), or even by persons holding a medical diploma. That the charlatans without professional training are a public menace will be admitted without question. Forty-five countries, including the United States and Canada, have adopted legal measures for the suppression of charlatanry. The law most frequently invoked is that prohibiting the illegal practice of the art of healing. In Europe, the crusade against the illegal practice of medicine is the best organized in France, but the charlatan with a medical diploma is not reached by the law. In Spain, advertising by charlatans is suppressed by law. There are two types of legislation against charlatanry in Europe, that of Germany and that of Great Britain. But in Germany there is no law prohibiting the illegal practice of medicine. There are, however, legal provisions prohibiting charlatanry in the matter of venereal diseases. In other countries (Brazil, Australia, Canada and Cuba) laws prohibiting charlatanry have been promulgated, but they are not always well enforced.

Center for the Instruction of Diabetic Patients

Rahier and van Themsche report, in the *Brussels medical* the organization of a therapeutic and prophylactic service for diabetic patients. As diabetes is widespread, the authors thought that therapeutic and prophylactic measures might be adopted against this disease the same as against venereal diseases. The benefits of this therapeutic organization will be felt by the people as a whole. As a result, diabetic patients will no longer constitute a heavy load for the health insurance societies, the patient receives proper training in caring for himself, and a periodic examination of patients under supervision is carried out. The authors hold that the capacity of diabetic persons scientifically supervised justifies their employment in occupations not requiring too intense muscular work. Diabetic persons no longer constitute "dead timber" in the labor market. They can perform the duties of an occupation that is not too fatiguing, provided they realize the importance of the role of insulin and of a well regulated diet and will follow strictly the prescriptions and the advice of their physicians.

Marriages

- E. DONALD ASSELIN, Nashua, N. H. to Miss Valeria Elizabeth Bergmann of New York, March 5
 WILLIAM R. BEACH, JR., Hudson, N. C., to Miss Myrtle Elizabeth Poole of Stoneville, April 10
 ROBERT R. SHAW, New York, to Miss Ruth Conser of Salem, Ohio, at Toccoa Falls, Ga., April 6
 AMOS VASTINE PERSING, JR., Allenwood, Pa., to Miss Varissa Payne of Pittsburgh, March 21
 JAMES EUGENE STROH, Seattle, to Miss Alyce Lorraine Lewis of Fresno, Calif., February 27
 VIRGIL O. CHOATE, Galax, Va. to Miss Millie S. Gilbert, at Patrick Springs, April 18
 THOMAS J. VAN ZANT to Miss Jane Amerman, both of Houston, Texas, March 5
 DAVID PAINE, Worcester, Mass., to Miss Mary Page Teele of Marblehead, April 13
 SAMUEL J. BURROWS, Chicago, to Miss Margaret Palmer of New York, April 24
 LEOPOLD ADLER to Miss Regina Silberstein both of Detroit, March 17

Deaths

Frank Swift Bourns * Seattle, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1896, in 1896 professor of pathology and bacteriology, Southern Medical College, Atlanta, veteran of the Spanish-American War, president of the board of health of Manila, P I, in 1899, and commissioner of public health of the Philippines in 1902, chief medical inspector for the health department of Seattle in 1909, member of the Radiological Society of North America aged 68, on the staff of the Columbus Hospital, where he died March 17, of coronary sclerosis and acute myocarditis

John Aloysius Reidy * Albuquerque N M, Jefferson Medical College of Philadelphia, 1903 also a dentist, fellow of the American College of Surgeons, formerly member of the city council and board of health, on the staffs of St Joseph Sanatorium and Hospital and the Southwestern Presbyterian Sanatorium, secretary-treasurer of the board of regents of the University of New Mexico from 1919 to 1926 aged 63, died, February 20, in Rochester, Minn, of carcinoma of the colon and bronchopneumonia

George William Cale Jr, Texarkana Texas St Louis College of Physicians and Surgeons 1887 fellow of the American College of Surgeons member of the State Medical Association of Texas, veteran of the Spanish-American War aged 68 chief surgeon and superintendent of St Louis Southwestern Hospital, Texarkana, Ark formerly on the staff of St Luke's Hospital, St Louis, where he died, March 24 of complications, following an operation for gastric ulcer

James John Monahan, Chicago College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1904, member of the Illinois State Medical Society fellow of the American College of Surgeons clinical associate in orthopedic surgery, Loyola University School of Medicine, aged 58 on the staff of St Elizabeth's Hospital where he died, April 13, of coronary thrombosis

Thomas Glendenning Hamilton, Winnipeg, Manit, Canada Manitoba Medical College, Winnipeg, 1903 past president of the Manitoba Medical Association, fellow of the American College of Surgeons, formerly lecturer of clinical surgery at his alma mater, aged 61, on the staff of the Winnipeg General Hospital, where he died, April 7, of angina pectoris and coronary occlusion.

Talbert Benson Hughes, Jonesboro, Tenn Chattanooga Medical College, 1902, at one time member of the state legislature, for many years in the government service in charge of various hospitals in the Indian Service formerly head of the x ray department of the Veterans' Administration Facility Augusta Maine, aged 61, died March 21, of nephritis and arteriosclerosis

Clarence Francis Moriarty, Annapolis, Md Dalhousie University Faculty of Medicine Halifax, N S 1925 member of the Medical and Chirurgical Faculty of Maryland served during the World War formerly member of the state departments of health in Maryland, Virginia and the Philippines, aged 37, died, January 14, of glioma of the left temporoparietal lobe

Joseph Raye Shuman * Los Angeles Gross Medical College, Denver, 1902 assistant clinical professor of medicine (pediatrics) University of Southern California School of Medicine member of the American Academy of Pediatrics, on the staff of the Children's Hospital aged 54 died March 9, in the Good Samaritan Hospital, of coronary thrombosis

Luther Conklin Payne * Liberty, N Y, University of Buffalo School of Medicine, 1900 councilor of the Third District of the Medical Society of the State of New York, secretary of the Sullivan County Medical Society, for many years health officer of Liberty aged 57 died March 16, of influenza and pneumonia

Frank Raynor de la Vergne * Fairbanks, Alaska Long Island College Hospital Brooklyn 1893 past president of the Alaska Territorial Medical Association, at various times mayor served during the World War, on the staff of St Joseph's Hospital, aged 68, died March 27, of diabetes mellitus

Eli Lide Dawson, Chickasha Okla University of Louisiana Medical Department New Orleans 1883 Jefferson Medical College of Philadelphia 1888 member of the Oklahoma State Medical Association city health officer on the staff of the Chickasha Hospital aged 79 died February 8

John Wesley Cram * Colrain Mass University of Vermont College of Medicine Burlington 1888 past president of

the Franklin County Medical Society for many years secretary of the board of health of Colrain and member of the school board, aged 76, died, April 5, of pneumonia.

Frank Riley Burton, Barbourville, Ky, Lincoln Memorial University Medical Department, Knoxville, Tenn., 1911, member of the Kentucky State Medical Association, secretary of the Knox County Medical Society aged 52, died, March 12, of malignancy of the stomach and liver

Jacob Nathaniel Rape, Moss Point, Miss, Tulane University of Louisiana Medical Department, New Orleans, 1891, member of the Mississippi State Medical Association, secretary and past president of the Jackson County Medical Society aged 75, died, February 4

George Morris Hall, Brockton, Mass, Harvard University Medical School, Boston 1923, member of the Massachusetts Medical Society, served during the World War, aged 43, died suddenly, March 4 in the Boston Psychopathic Hospital, of cerebral edema

Brendan William Murphy, Bridgewater Mass, McGill University Faculty of Medicine, Montreal Que, Canada, 1923, served with the Canadian Army during the World War aged 39 died April 3, of hypertension, chronic myocarditis and nephritis

Frederick E Sonnenfeld, Chicago, Chicago Hospital College of Medicine 1917, member of the Illinois State Medical Society on the staff of the Roseland Community Hospital aged 47 died, April 12, in the Passavant Memorial Hospital, of uremia

Charles H Johnson * Atchison, Kan, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895, on the staff of the Atchison Hospital, aged 65, died suddenly, April 3, of heart disease.

Charles E Fish, Wheatland Wyo, Drake University College of Medicine, Des Moines, 1907, member of the Wyoming State Medical Society, aged 55, died, February 11, in Denver of peritonitis and carcinoma of the bladder

Karl William Schlegel * Milford Ill, University of Illinois College of Medicine, Chicago, 1932, aged 36, died, April 13, in the Lutheran Deaconess Home and Hospital, Chicago, of injuries received in an automobile accident

Frank Thoburn Nason, McKeesport, Pa, Western Pennsylvania Medical College Pittsburgh, 1889, Bellevue Hospital Medical College, New York, 1894, aged 68 died, April 4, of thrombosis of superior mesenteric vessels

Manuel Winter Jackson, Water Valley, Miss, Tulane University of Louisiana Medical Department New Orleans, 1900, member of the Mississippi State Medical Association, aged 70, died, March 9, of pneumonia

John Webb Decker, Lake City, Mich, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1887 formerly village president, village clerk and coroner, aged 72, died, March 19, of myocarditis

Robert C Droege, Lakewood Ohio, Western Reserve University Medical Department, Cleveland 1897 member of the Ohio State Medical Association, aged 60, died suddenly, March 17, of coronary thrombosis

Maurice A Bunce, Philadelphia University of Pennsylvania Department of Medicine, Philadelphia, 1893, member of the Medical Society of the State of Pennsylvania, aged 61 died March 19, of heart disease.

John Ross Jameson * Wooster, Ohio, Medico-Chirurgical College of Philadelphia, 1894, past president and secretary of the Wayne County Medical Society, aged 69 died, February 28 of bronchopneumonia

James Harvey Cleaver, Los Angeles University of Maryland School of Medicine, Baltimore 1880 formerly mayor of Council Bluffs, Iowa aged 78, died, February 7 in the California Lutheran Hospital

Louis Lucien Rabouin * New Orleans Tulane University of Louisiana Medical Department New Orleans 1892, aged 68, died February 25, in the Touro Infirmary, of arteriosclerotic heart disease

George Richard Sullivan, Decatur Ala Shelby Medical College Nashville Tenn, 1859 member of the Medical Association of the State of Alabama, Confederate veteran, aged 97 died, February 14

Robert C Newell, Maywood Ill, State University of Iowa College of Homeopathic Medicine Iowa City 1879 aged 84 died April 7 in the Cook County Hospital, Chicago of chronic nephritis and uremia

Simril McDowell Henderson, Charlotte N C University of Maryland School of Medicine, Baltimore, 1894, aged 65, died April 12, in the Highsmith Hospital, Fayetteville, of cerebral hemorrhage

Thomas K Jacobs Jr, Lima Ohio Medical College of Ohio, Cincinnati 1880, aged 79, died, March 14, in the Lima Memorial Hospital, of arteriosclerosis, infection of the foot and myocarditis

Benjamin Junius Cooke, Indianapolis Meharry Medical Department of Central Tennessee College, Nashville, 1890, aged 71 died March 22 in the Community Hospital, of chronic myocarditis

Wiley Moroni Cragun, Ogden Utah, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1911, aged 50, died, February 18, of coronary thrombosis

Henry Bohan Noble, Howard, S D, Missouri Medical College St Louis 1882, for many years county health officer, aged 86 died, January 10, in Manchester, Iowa, of coronary thrombosis

Gebhard Joseph Long Jr, Ramona, S D Rush Medical College Chicago 1909 member of the South Dakota State Medical Association, aged 49, died, February 22, of lobar pneumonia

Glenn Robert Longnecker, Washington C H Ohio Eclectic Medical College Cincinnati 1922 aged 43, died February 21, in the Veterans' Administration Facility Dayton, of pneumonia

Emilie E Sullivan Rauch, Belvidere, S D, Sioux City (Ia) College of Medicine, 1903, county health officer, aged 71 died, January 31, of carcinoma of the cervix and myocarditis

Charles Arthur Gardiner, Sunset, La Tulane University of Louisiana Medical Department, New Orleans 1896 member of the Louisiana State Medical Society, aged 62, died, February 15

Richard Nathan Mackey, Clarks Summit, Pa, Medico-Chirurgical College of Philadelphia 1910, served during the World War, deputy coroner, aged 47, died, April 1, of pneumonia

John Genar Ash, Mount Sterling Ill Kentucky School of Medicine, Louisville 1896 member of the Illinois State Medical Society, aged 66, died, March 17, of lobar pneumonia

Solomon Myers, Boston Harvard University Medical School, Boston, 1900 member of the Massachusetts Medical Society, aged 62 died January 18, of coronary thrombosis

Livingston Franklin Johnson, Dillon S C, Jefferson Medical College of Philadelphia, 1905, aged 57, died, April 4, in the McLeod Infirmary, Florence, of coronary occlusion

Carl August Dreiss, Fort Worth, Texas, Ensworth Medical College, St Joseph, Mo, 1889, served during the World War, aged 71, was found dead, March 20, of heart disease

Samuel T Sealy, Mounds, Ill Meharry Medical College Nashville, Tenn 1909 member of the Illinois State Medical Society, aged 50, died, March 3, of cerebral hemorrhage

William Peter Smith, Troy, Mo Beaumont Hospital Medical College, St Louis, 1893, member of the Missouri State Medical Association, aged 64, died, February 8

Peter James Parker, San Diego, Calif, Jefferson Medical College of Philadelphia, 1871, member of the California Medical Association, aged 89, died, March 15, of myocarditis

Bert Martin Johnson, Imola, Calif St Louis University School of Medicine, 1925, on the staff of the Napa State Hospital, aged 43, was found dead in bed, February 28

Joseph Henry Cosgrove, Duluth, Minn., University of Minnesota Medical School, Minneapolis, 1906, aged 55, died, February 7, of coronary occlusion and myocarditis

William Sellman Welch, Annapolis Md, College of Physicians and Surgeons Baltimore, 1885, formerly health officer of Annapolis, aged 81, died, February 11

Charles Emerson Jones Jr, Hartford, Conn, University of Bellevue Hospital Medical College, New York, 1909, aged 50 died, January 24, of coronary thrombosis

William M Browder, Gallion, Ala Jefferson Medical College of Philadelphia 1888 formerly state senator, aged 71, died suddenly, March 21, of heart disease

Noble Butler Parvin, Indianapolis, Jefferson Medical College of Philadelphia, 1891 aged 77 died, March 4, in the Methodist Hospital, of lobar pneumonia

Charles W Schaub, St Louis Missouri Medical College St Louis 1894 member of the Missouri State Medical Association, aged 67 died, February 3

Isidore Charles Eisenberg ⊕ New York University of Vermont College of Medicine, Burlington, 1891, aged 67, died, March 23, of coronary occlusion

Benjamin Frank Ogden, Clayton, N J, Medico Chirurgical College of Philadelphia 1905, aged 55, died, April 8 of pyemia following infection of the finger

William H Nicholson, Henderson, N C., University of Maryland School of Medicine, Baltimore, 1889, aged 70 died, April 8, of chronic nephritis

John Whitman Joslin, Johnstown, N Y, Albany (N Y) Medical College, 1891, for many years county coroner, aged 81, died, March 4, of carcinoma

Leslie John Katonah ⊕ Flushing, N Y Deutsche Universität Medizinische Fakultät, Prague, Czechoslovakia, 1914, aged 35, died, February 22

Joseph Francis Piotrowski, Cleveland, Ohio State University College of Homeopathic Medicine, Columbus, 1918, aged 40, died, February 1

Alvin Charles Tanner ⊕ Minneapolis Rush Medical College, Chicago, 1910 aged 59, died, February 13, in the Minneapolis General Hospital

Roy Farnsworth Hockett ⊕ Independence, Mo University of Kansas School of Medicine, Kansas City, 1927, aged 32 died, February 17

William A Lynott, Plymouth, Pa, Louisville (Ky) Medical College 1907, aged 55, died March 28, in Scranton, of coronary sclerosis

Charles Luther Dreese, Goshen, Ind Fort Wayne (Ind) College of Medicine, 1881, aged 86, died, March 27, of cerebral hemorrhage

Elijah P Gibson, Louisville Ill Hospital College of Medicine Louisville Ky, 1878, aged 84 died, March 3 of myocarditis

Eli Elias Carlton, Ringgold, Texas, Kentucky School of Medicine, Louisville, 1897, aged 68, died, March 10, of nephritis

George Everette Loverette, Cincinnati, Leonard Medical School, Raleigh 1902, aged 65, died, February 8, of diabetes mellitus

Harrison H Norris, Whitewater, Kan Eclectic Medical Institute, Cincinnati, 1885, aged 73, died, March 17, of heart disease

John Julian Paul, Georgetown Ont Canada, Trinity Medical College, Toronto 1885, aged 71, died, February 19, of heart disease

Charles Albert Milton, Dodge City, Kan. Rush Medical College Chicago, 1881, aged 82, died, March 2, of angina pectoris

Raye S Everett, Bay City, Mich, Cleveland University of Medicine and Surgery, 1895, aged 70, died, March 9, of heart disease

John Henry Dangerfield, Wheeling, W Va, Meharry Medical College, Nashville, 1925, aged 37, died, March 31, of uremia

George E Orth, Freeland, Mich, Michigan College of Medicine and Surgery, Detroit, 1904, aged 59, died, February 16

Samuel James Farrell, Holden, Alta, Canada Trinity Medical College, Toronto, Ont, 1900, aged 68, died, January 3

Albert Ladislav Kiraly, Cleveland Eclectic Medical College of the City of New York, 1902, aged 58 died, February 6

James Thornburg Turner, La Follette, Tenn Tennessee Medical College, Knoxville, 1899, aged 76, died, February 13

Michael Rokosz, Rosebud, Mo, St Louis College of Physicians and Surgeons, 1918, aged 43, died, in February

Joseph O Glenn, Stroud Okla. Ensworth Medical College, St Joseph, Mo 1882, aged 75 died, February 9

William H McMillan, Erin, Tenn (licensed in Tennessee in 1889), aged 75, died recently, of bronchopneumonia

William Collins Hanson, Auburn, Ala., Atlanta Medical College, 1889, aged 69, died, February 4

CORRECTION

Obituary Notice—The statement in the obituary notice in THE JOURNAL, April 13 that Dr Thomas Cook Stellwagen had been president of the American Association of Genito-Urinary Surgeons was erroneous. Dr Stellwagen had not been president of this association.

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product (2) the name of the manufacturer, shipper or consigner (3) the composition (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

Dennos Food—Dennos Food Co Portland Ore Composition Essentially wheat flour bran and sugar For infant feeding indigestion heart burn flatulence insomnia ulcers etc Fraudulent therapeutic claims—[N J 21177 August 1934]

Rayburn's Easy Antiseptic—W S Rayburn & Sons Chicago Composition Essentially petrolatum with small amounts of benzaldehyde camphor and a coloring material For boils eczema cancer rheumatism etc Fraudulent therapeutic claims—[N J 21180 August 1934]

Tachar's Diarrhoea Mixture—Allied Drug Products Co Chattanooga Tenn Composition Essentially small amounts of plant drug extracts including tannin and inorganic material including an iron compound with large amounts of glycerin and water flavored with clove oil Fraudulent therapeutic claims—[N J 21182 August 1934]

Grimes Ointment—Grimes Ointment Co Los Angeles Composition Essentially volatile oils including camphor with reducing sugars such as honey and glycerin rosin and opium extract in an ointment base such as petrolatum and tallow For blood poison piles ulcers etc Fraudulent therapeutic claims—[N J 21183 August 1934]

Kap Oil—Kap Oil Co Broken Bow Neb Composition Essentially petrolatum with phenolic compounds menthol oil of wintergreen and a minute amount of a mydriatic alkaloid colored with a green dye For pneumonia influenza asthma etc Fraudulent therapeutic claims—[N J 21184 August 1934]

Joy's Castoria—Mills Soles Co New York City Composition Essentially extracts of plant drugs including a laxative with sugar glycerin alcohol and water For colic diarrhea worms etc Fraudulent therapeutic claims—[N J 21186 August 1934]

Witter Water—Witter Water Co Ukiah Calif Composition In each quart 177 grains of dissolved mineral matter consisting essentially of sodium, magnesium and calcium bicarbonates borax common salt and small amounts of other salts commonly present in ground water For acid stomach etc Fraudulent therapeutic claims—[N J 21188 August 1934]

Thor's Vitamin Compound—Thor Pharmaceutical Co Atlanta Ga Composition Tablets containing plant material including nux vomica and a laxative drug with compounds of iron and copper phenolphthalein and yeast. Worthless as a source of vitamin D For 'run-down condition etc. Fraudulent therapeutic claims—[N J 21189 August 1934]

Andas Great Oil—Crump Laboratories Louisville Ky Composition Essentially ammonia oils of red pepper cloves and eucalyptus with camphor traces of sodium carbonate and an iron compound alcohol (14.9 per cent by volume) and water For rheumatism backache pleurisy etc Fraudulent therapeutic claims—[N J 21191 August 1934]

Fishers Lung Balm and Household Ointment—George L Fisher Superior Neb Composition Essentially volatile oils including eucalyptol incorporated in petrolatum For coughs catarrh croup tonsillitis etc Fraudulent therapeutic claims—[N J 21193 August 1934]

Normalettes—Health Laboratories Inc Long Beach Calif Composition Tablets containing ground plant material coated with calcium carbonate and sugar The Group 2 Normalettes containing in addition small portions of phenolphthalein and bile salts and the Group 3 Normalettes containing in addition a starch digestant charcoal and baking soda Fraudulent because the various Groups were represented as remedies for various diseases—[N J 21198 August 1934]

Alhna Tea—Health Laboratories Inc Long Beach Calif Composition Essentially milk sugar (97 per cent) and a small amount of plant material For normalizing the body Fraudulent therapeutic claims—[N J 21198 August 1934]

Burbank Tea (Dried Alfalfa)—California Vegetized Products Co Burbank Calif Composition Dried alfalfa For poor blood nervous disorders etc. Fraudulent therapeutic claims—[N J 21199 August 1934]

Anticol—Apex Laboratories Inc New York City Composition Essentially volatile oils (19 per cent) including menthol and lavender oils and approximately 79 per cent of alcohol A vaporous inhalant Misbranded because quantity or proportion of alcohol not declared on label—[N J 21204 August 1934]

Merrell's Penetrating Oil—Dick Dunn Drug Products Co St Louis Composition Essentially volatile oils including turpentine oil and eucalyptol For toothache earache cramps rheumatism etc Fraudulent therapeutic claims—[N J 21205 August 1934]

Yoh i Ana Dulce—Dulce Laboratories Dallas Tex. Composition Essentially petrolatum with small amounts of volatile oils such as citronella and peppermint, and a rubefacient such as red pepper extract For sexual impotency Fraudulent therapeutic claims—[N J 21206 August 1934]

Bromo Paper—Diamond Mills Paper Co New York City Composition Essentially tissue paper impregnated with a small amount of mineral oil and a very small proportion of carbolic acid For hemorrhoids Fraudulent therapeutic claims—[N J 21208 August 1934]

Eyetex—Mills Sales Co New York City Composition Essentially table salt baking soda and borax with small amounts of thymol sodium benzoate sodium eucalyptate and hydrastine colored yellow For eye disorders Fraudulent therapeutic claims—[N J 21209 August 1934]

Alberty's Calcetine—Composition Tablets composed essentially of milk sugar with minute amounts of inorganic material including calcium salts phosphate sodium potassium iron magnesium and chlorine compounds Tonic Fraudulent therapeutic claims—[N J 21210 August 1934]

Alberty's Lebra Organie Pellets (Formerly Liver Cell Salts)—Composition Essentially milk sugar with minute amount of inorganic material principally calcium salts with traces of sodium potassium iron, magnesium and chlorine compounds For malaria biliousness diabetes etc Fraudulent therapeutic claims—[N J 21210 August 1934]

Catalyn—Vitamin Products Co Milwaukee Wis Composition Essentially plant material including wheat bran wheat starch glandular material including epinephrine, with milk sugar Cure all Fraudulent therapeutic claims—[N J 21213 August 1934]

Ablena Crystals—Ablena Co Ablena Kan Composition Essentially dried Glauber's salt with small quantities of epsom and common salt For radiant health constipation and its resultant effects Fraudulent therapeutic claims—[N J 21215 August 1934]

Apge Capsules—Hance Bros & White Inc Philadelphia Composition In each capsule a pellet containing extracts of plant drugs including oil clove and a liquid containing oils such as sassafras and parsley For female disorders Fraudulent therapeutic claims—[N J 21217 August 1934]

Golden Rheumatism Remedy—C J McCormick Fort Worth Texas Composition Essentially an extract of a laxative plant drug small quantities of potassium iodide and a salicylate with alcohol (19 per cent) sugar and water Fraudulent therapeutic claims—[N J 21218 August 1934]

Golden Blood Tonic—C J McCormick Fort Worth Texas Composition Essentially potassium iodide iron strychnine a small quantity of quinine with such plant extracts as sassafras and podophyllum and a laxative drug such as rhubarb Fraudulent therapeutic claims—[N J 21218 August 1934]

Golden Cough Compound—C J McCormick Fort Worth Texas Composition Essentially tar a trace of chloroform alcohol (4.4 per cent) and water Misbranded because label lacked declaration of quantity or proportion of alcohol present also fraudulent therapeutic claims—[N J 21218 August 1934]

Golden Laxative Cold Tablets—C J McCormick Fort Worth Texas Composition Essentially acetanilid quinine sulphate (1/40 grain per tablet) and plant extracts including red pepper and a laxative Fraudulent therapeutic claims—[N J 21218 August 1934]

Alberty's Anti Diabetic Vegetable Compound—Alberty Food Laboratories Hollywood Calif Composition Essentially powdered plant materials Fraudulent therapeutic claims—[N J 21220 August 1934]

G C C Golden Chemical Compound—International Chemical Co., Topeka Kan Composition Iron sulphate dissolved in water For diphtheritic and scarlet fever sore throat pyorrhea catarrh eczema erysipelas bleeding piles etc Fraudulent therapeutic claims—[N J 21222 August 1934]

Carlitol Comp Tablets—Raymer Pharmacal Co Philadelphia For Indigestion etc Misbranded because of fraudulent therapeutic claims and because each tablet contained less than the 1/2 grain of salol represented—[N J 21223 August 1934]

Edrelax—Edros Natural Products Inc New York City Composition Essentially a mixture of mucilaginous seeds including psyllium with agar agar and caramel For constipation intestinal inflammation etc Fraudulent therapeutic claims—[N J 21226 August 1934]

Wonder Crystals—Wonder Crystals Product Co., Holdrege Neb Composition Essentially crystallized Glauber's salt Cure all Fraudulent therapeutic claims—[N J 21237 August 1934]

Live On Tonic—Live-On Medicine Co St Louis Composition Essentially rhubarb extract tar vinegar alcohol and sirup For coughs catarrh asthma etc Fraudulent therapeutic claims—[N J 21227 August 1934]

Burbank Kelp—Vegetable Products Corporation Burbank Calif Composition Essentially ground seaweed For nervousness rheumatism asthma anemia and digestive troubles Fraudulent therapeutic claims—[N J 21231 August 1934]

INFECTION WITH TUBERCULOSIS

To the Editor—Where can I get the latest information on the following questions regarding tuberculosis? 1 Does the primary infection of tuberculosis increase the immunity of an individual to further exogenous infection with the bacillus of tuberculosis? 2 What is the length of life of the bacillus of tuberculosis under different conditions as in sunlight and in dark rooms? 3 Is there any age beyond which it is considered that an individual will not become infected with tuberculosis? Please omit name and address.

M D Wisconsin

ANSWER—1 There is good experimental evidence to show that the animal body after having been infected with small doses of tubercle bacilli or with those of low virulence, will later tolerate large doses of tubercle bacilli longer than the animal that has not been previously infected. This greater length of life has been attributed to immunity produced by the original infection (Kruse, A. K. *J. M. Research* 35:25 [Sept.] 1916; Willis, H. S. *Am. Rev. Tuberc.* 17:240 [March] 1928). From such work it was deduced that the child who became infected with tubercle bacilli and was not ill, developed immunity to tuberculosis, and it was this immunity which accounted for the extremely low morbidity and mortality from tuberculosis in children. Recent observations have shown, however, that when these so-called immunized children approach the period of puberty some of them fall ill from clinical tuberculosis and by the time they reach the age of 21 years approximately 10 per cent have developed tuberculosis in one of its clinical forms (Myers, J. A. and Harrington, F. E. *The Effect of Initial Tuberculous Infection on Subsequent Tuberculous Lesions* *THE JOURNAL*, Nov. 17 1934 p. 1530). In all probability as many more of the group who were infected in childhood will fall ill before they have reached the average length of life of the general population. Just how many of this 10 to 20 per cent of infected children who later fall ill develop their clinical tuberculosis through exogenous reinfection is not known. The fact is well established however that when tubercle bacilli escape in sufficient numbers from old primary foci and find lodgment on allergic tissues they are capable of producing disease. There is no evidence to show that such bacilli are any more likely to cause disease than those introduced into the bodies of sensitized persons from exogenous sources. Experimental workers (Burke, H. E. *Tr. Nat. Tuberc. A. 29th Annual Meeting*, 1933 p. 212) have proved that immunized animals develop a destructive form of disease when tubercle bacilli are introduced from exogenous sources. Therefore the primary infection with tuberculosis may produce some immunity to tubercle bacilli either from endogenous or from exogenous sources. Unfortunately however one cannot depend on this immunity since it is only the previously infected human beings, and those who should be immunized by such infection who actually develop chronic clinical tuberculosis.

2 The length of life of the tubercle bacillus outside the human body varies a great deal, depending on its exposure to direct sunlight. If in sputum and partially covered by dust, even though in places where there is abundant sunshine, the tubercle bacillus is adequately protected so that it may remain alive for many days. When exposed to the direct rays of the sun cultures of tubercle bacilli are rendered sterile in approximately two hours. When sputum is spread thinly on glass, only ten minutes of direct sunlight is required to kill them. Material containing tubercle bacilli placed on linen and woolen cloth and dried have lost their ability to infect animals after twenty-four to thirty hours of exposure to daylight. When one exposes tubercle bacilli to rays from the mercury quartz vapor lamp they lose their acid-fastness in a few minutes and are dead in ten minutes. When sputum containing tubercle bacilli is smeared thinly on cloth or glass and dried in a dim light in a cool place, they remain alive and virulent as long as four months. When bacilli are exposed to diffuse light, as in a house, they have been found virulent as long as thirty-nine days.

3 Apparently there is no age at which the individual will not become infected with tubercle bacilli. At one time it was believed that all initial infection occurred in childhood, perhaps it did. However with the reduction in the number of sources of tubercle bacilli through pasteurization of dairy products, slaughter of tuberculous animals, isolation, treatment, and education of tuberculous human beings the children of most communities no longer become contaminated in large numbers.

In fact there are many places in this country where from 75 to 90 per cent of the children enter the period of puberty without having been infected with tubercle bacilli. When some of these uninfected individuals later become exposed to tubercle bacilli, such as frequently occurs in students of nursing and medicine, they are seen to develop the first infection type of tuberculosis which is not essentially different from that which they would have developed if they had been infected in infancy or childhood (Myers, J. A. *Am. Rev. Tuberc.* 23:93 [July] 1933). There are cases on record of much older individuals who have become infected for the first time and who developed the characteristics of the first infection type of disease as seen in childhood. The reinfection type of tuberculosis whether from endogenous or exogenous sources can take place at any time in life. The best evidence to support this statement is the increased incidence of the reinfection type of tuberculosis in the human family as the decades advance, that is in the second decade of life there is far more clinical tuberculosis than in the first, there is more in the third decade than in the second and so on throughout the decades of life. After the age of 50 for the number of people living the incidence of clinical tuberculosis is higher than at any other age period in life. This fact has been established not only through surveys that include x-ray films and sputum examinations but also through postmortem studies.

INJECTION TREATMENT FOR HERNIA

To the Editor—Is the treatment of hernia by injection of sclerosing solutions a sound procedure? This matter has been recalled to my attention through the recent promotion of Pina-Mestre's Solution proposed for that purpose.

M D Arkansas

ANSWER—Pina-Mestre's Solution, manufactured by Dr. E. Pina-Mestre of Barcelona, Spain, was declared not acceptable for inclusion in New and Nonofficial Remedies (*THE JOURNAL*, Feb. 1 1930, p. 339). At that time, however, it was known as *Hernial* (Inyecciones Proliferantes Obstruidoras del Dr. E. Pina-Mestre). The formula was then stated to be as follows:

Each ampule contains approximately 98% of alcohol and the balance consists of the following ingredients expressed in percentages: 25% Krameria 16% Catechu 15% Rosa Canina 15% Rosa Centifolia 14% Vaccinium Myrtillus 15% Monea.

The attempted cure of hernia by the application of John Hunter's theory of "adhesive inflammation" is not new nor original with Dr. Pina-Mestre. Injection of irritants of varying sorts into the inguinal canal was performed successfully almost a century ago by Velpeau.

The results obtained perhaps compared favorably at that time with those following surgical repair, but it must be remembered (1) that aseptic surgery was then unknown and (2) that infection of herniography wounds predisposes greatly to recurrence. The indiscriminate spreading of severely irritant substances throughout an area containing such delicate structures as the inguinal canal with the frequent presence in the sac of intestine, omentum, bladder, ovary or other abdominal viscera is most hazardous. Once the substance is injected, its distribution is beyond control. While dense scar formation might be eminently desirable at a given site, it might be equally objectionable in another area. For example any substance that will produce adhesions in the inguinal canal around the hernia may produce adhesions in the peritoneal cavity, which is continuous with the hernial sac. Because this procedure is advocated for office use, the occurrence of perforation of the bowel with peritonitis, of some viscus, of the deep epigastric artery (in inguinal hernia) or even of the femoral artery itself (in femoral hernia) is particularly dangerous. It would be most difficult to effect ligation of either of these vessels in the office of the general practitioner. Yet such injury would constitute an urgent surgical emergency.

It may be said that after the recognized operations for hernia the normal anatomy of the region is somewhat altered but the result is practically as satisfactory, structurally and functionally, as the normal. The results produced by sclerosing solutions injected into this area would defy prediction and would undoubtedly produce more or less distortion of all immediately adjacent structures with perhaps sterility in the male and with no assurance that the hernia would be cured or even affected.

While there would appear to be no place at all for the injection treatment, it is possible that in the case of very aged individuals, or those whose physical state would contraindicate operation, there may occur isolated instances in which an attempt at treatment of this sort might be justified if the patient fully understands the dangers. Any common irritant would undoubtedly serve as well as Pina-Mestre's Solution and at a considerable saving (the price, to physicians of 60 cc of the preparation is \$20). It is probable though that, whenever

surgery is contraindicated, injection would also be unwise by reason of the possible occurrence of the previously noted complications, any one of which might require immediate operation on a poor-risk patient. For such individuals, a well fitted and frequently adjusted truss may prove satisfactory.

The large or unreducible hernias are the ones that are not always repaired satisfactorily, especially by the inexperienced surgeon, but these could never be safely relieved by injections.

In general, surgical repair by a well trained surgeon offers a satisfactory method for the treatment of hernia with a minimum of local tissue injury and little risk or discomfort.

TRINITROPHENOL (PICRIC ACID) METHOD FOR STAINING TUBERCLE BACILLI

To the Editor—I would appreciate the technique of Pottenger's dilution flotation picric acid method for examining specimens for tubercle bacilli.
WALTER T SWINK M D Memphis Tenn

ANSWER.—The Pottenger dilution—flotation—trinitrophenol (picric acid) method for examining sputum for tubercle bacilli is performed in the following manner:

1 Collect the sputum for from twenty-four to seventy-two hours.

2 Add an equal part of 0.5 per cent sodium hydroxide solution and then shake, preferably with a shaking machine, for from five to ten minutes. Shaking can also be done by hand.

3 Digest in a water bath at 55 C for from thirty minutes to one hour.

4 Pipet off and discard any insoluble residue that has settled to the bottom of the bottle.

5 Add from 1 to 2 cc of a hydrocarbon (xylene, ligroine, benzene or gasoline). Fill with distilled water to about 200 cc. Shake for ten minutes.

6 Allow the hydrocarbon to collect at the top of the bottle (from ten to twenty minutes).

7 If the viscosity of the specimen is too high, remove the supernatant fluid by a sterile siphon, fill to 200 cc again with distilled water, and shake for five minutes.

8 When the viscosity is practically that of water, the supernatant hydrocarbon layer is drawn up in a sterile pipet, which is pinched by inserting a cork, and allowed to remain in the vertical position until the liquid separates from the hydrocarbon layer (from five to ten minutes). The supernatant liquid is discarded and smears are made from the hydrocarbon layer. This is put on the slide and dried layer on layer to the desired thickness.

9 Wash the smear in ether to remove traces of hydrocarbon and fat. Stain as usual. In decolorizing with acid alcohol do not allow more than twenty seconds exposure, as bacilli decolorize rapidly. Complete the decolorizing with from 5 to 10 per cent sodium sulphite if necessary. Counterstain with 1 per cent aqueous trinitrophenol solution.

For proper films, from two to five large drops of the layer are necessary. The preparations are thin and clean and do not peel. Some rare purulent sputums require a dilution of 1 to 100 or more before the hydrocarbon layer forms distinctly.

The foregoing method attempts to break up all clumps of bacilli so that they are distributed equally and singly throughout the specimen, and then concentrated in a small quantity. Thus they are much more apt to be found.

Whereas the ordinary technique of staining smears of sputum is positive only with 100,000 or more bacilli per cubic centimeter (Dr H J Corper), this method is said to demonstrate tubercle bacilli in numbers as low as 1,000 in a twenty-four hour quantity of sputum. The method is about 200 times as sensitive as the ordinary sputum smear technique. It is about as accurate as guinea pig inoculation and can be carried out in about two hours. From 200 to 500 bacilli per cubic centimeter can be detected after a ten minute search of the smear.

URETHRITIS AND VESICULITIS AFTER GONORRHEA

To the Editor—Give treatment for a chronic though mild posterior urethritis and seminal vesiculitis following gonorrhea about five years before. It is stated by some that if the vesiculitis can be cured the posterior urethritis will cure spontaneously; others state that if the urethritis is cured the cure of the vesiculitis will follow of itself. Which view is correct or are both statements correct? Please omit name and address.
M D Texas

ANSWER.—The recognized treatment of chronic prostatitis and seminal vesiculitis following gonorrhea is routine massage of these organs and instillation of a mild solution (from 0.5 to 1 per cent) of silver nitrate. At the present time some are making direct injection of certain chemicals into the gland either transurethrally or transrectally. This method is still in the experimental state. There is no reason to believe the cor-

rectness of the statement "It is stated by some that if the vesiculitis can be cured the posterior urethritis will cure spontaneously, others state that if the urethritis is cured the cure of the vesiculitis will follow of itself."

SARCOMA OF ILEUM

To the Editor—Would you please tell me the frequency of sarcoma of the ileum particularly the terminal ileum. I have a case now in which I operated ten days ago for an acute surgical condition of the abdomen and found a large tumor of the terminal ileum which had broken through and formed a large colonic abscess outside the bowel. I resected and the report from the pathologist came back intermediate spindle cell sarcoma. The patient did not have a symptom until two days before the operation. Are these cases frequent? Have you any statistics on this condition? What is the percentage of recurrence? Please omit name.
M D Tennessee

ANSWER.—Sarcoma of the terminal ileum is an uncommon condition. On account of the uncertainty as to the precise histology and histogenesis of these lesions, the literature on this subject is indefinite. It is not clear from many of the reports in the literature as to whether one is dealing with lymphosarcoma, spindle cell sarcoma or myosarcoma. Lymphosarcoma is the most common of the three. The myosarcomas in this region usually arise in the submucosa of the appendix and cecum and frequently give rise to the clinical picture of acute appendicitis. Goldstein reports statistics from Prague in which thirteen intestinal sarcomas were observed over a period of fifteen years among 13,036 necropsies, representing an incidence of 0.1 per cent. The same author was able to collect 627 cases of intestinal sarcoma in the world literature. Three per cent located in the appendix. Spindle cell sarcomas constitute about 13 per cent of all types of intestinal sarcoma. Rankin states that patients operated on for intestinal sarcoma generally die within the first year although occasionally the disease can be controlled and some five-year cures are recorded.

EPIDIDYMITIS

To the Editor—What part does trauma play in the production of acute epididymitis in a person who gives no history of a gonorrheal infection either recently or in the past? Is acute epididymitis ever metastatic to a colibacillary, staphylococcal, streptococcal or pneumococcal infection? How frequently is tuberculosis the cause of an acute epididymitis in which there is no history of gonorrhea or trauma and is it possible in such a case that one of the organisms named could be the cause of the epididymitis instead of tuberculosis? Please omit name and address in answer.
M D Pennsylvania

ANSWER.—Trauma may be the exciting cause of an acute nongonorrheal epididymitis in a person who gives no history of a gonorrheal infection. There are many infections of the epididymis, however, which are due to other organs and which reach the epididymis by extension along the vas deferens from the prostate and seminal vesicles. Acute epididymitis may be the site of a metastatic infection in a colibacillary, staphylococcal, streptococcal or pneumococcal infection, but if this occurs it is usually part of a general sepsis due to these organisms. Acute epididymitis may occur in tuberculosis of the epididymis and when it does it is usually an acute process engrafted on a preexisting tuberculosis. In other words, another example of a mixed infection. Any of the organisms named may cause this complication.

EFFECTS OF REMOVAL OF PROSTATE AND SEMINAL VESICLES

To the Editor—Will you please tell me the indications for and results from the removal of the prostate and seminal vesicles in a man aged 35? Is this ordinarily considered a formidable procedure and what would be the effects on the sex life of the individual? Please omit name and address.
M D Connecticut

ANSWER.—The only indication for this radical operation in a man aged 35 would be tuberculosis, and it is quite likely that a large percentage of good surgeons and urologists would not be inclined to do it. It is indeed a formidable procedure involving extensive dissection through the perineum. Young has devised an operation covering this procedure. The entire set of organs can be removed without opening the urinary tract.

The first effect on the patient would be to diminish considerably the seminal ejaculate, as the secretions from the prostate and vesicles would be absent, the psychic effect might be slight or considerable, depending on the personal equation and his reaction to the surgical procedure. Sexual ability might be altered slightly or greatly, again depending on the individual. Young says the operation is not dangerous to life even when nephrectomy is also necessary.

NO MEDICAL TREATMENT OF CATARACT

To the Editor—At the age of 64 an opacity of the lens is forming in one of my eyes and has been under observation for a year or more making slow progress. An ophthalmologist has urged during this period daily use of a solution of ethylmorphine hydrochloride in water one or two drops in the eye nightly. He does not promise anything more than a hope that it will prove efficacious in clearing up the opacity but urges its continuance. I find that the slight inflammation of the conjunctiva that it causes is I think sufficient to make the instillation of the drug hardly worth while unless there is good reason to believe that good will result. I may say that I have but one eye with which I can read and unfortunately the opacity has affected that eye. One or two other ophthalmologists that I have asked about this seem to consider the use of ethylmorphine hydrochloride or glycerin in borie acid solution of very questionable value and I should much like to know what the consensus of competent authorities—if there is any general agreement in the matter—is with regard to this. I do not question the competence of the ophthalmologist but in view of the rather serious nature of the trouble and the not altogether pleasant nature of the irritation set up by the drug I should like to know what confidence in it other ophthalmologists have. Please omit name and address if published in THE JOURNAL.

M D New York

ANSWER—For the past few years a committee from the Section on Ophthalmology of the American Medical Association headed by Dr. Allen Greenwood of Boston has been investigating the so-called medical treatment of cataract. The conclusion of the committee is that there is no known medical treatment that is of proved value. Individual ophthalmologists have reported cure or arrest of cataract with this or the other local or systemic treatment but none of these reports have been substantiated by others. In general it is not considered that the opacity of a lens can be influenced by the use of medicaments in the conjunctival sac.

THERAPEUTICS OF CASCARA

To the Editor—1 Is the best method of taking cascara sagrada regularly that of using small doses three times a day after eating? 2 Is there any harm in taking five drops of the bitter tincture of cascara in this manner over a period of years (provided a patient is satisfied with this form of laxative and refuses to change)? What ill effects might be expected? 3 Is there any therapeutic advantage of the aromatic tincture of cascara over the bitter? Please omit name and address.

M D Pennsylvania

ANSWER—1 When cascara sagrada is taken regularly for the purpose of increasing the irritability of the bowel it is better given three times daily half an hour before meals than after meals, as it will then have an opportunity to act in greater concentration than when mixed and diluted with the large bulk of stomach contents after a meal.

2 The constant taking of any stimulant is theoretically objectionable on the ground of habituation and the consequent necessity of progressive increase of dosage. In practice this does not always happen. It is nevertheless well to attempt gradual and progressive reduction of dose. If this is impossible beyond a certain point, taking recourse to alternation with a succedaneum, such as aloe, is advisable.

3 The aromatic fluidextract of cascara sagrada is much more palatable than the bitter fluidextract. Unfortunately, it is also less efficient, possibly in a 1:4 ratio.

NODULES ON JOINTS

To the Editor—I have under my care a man weighing about 200 pounds (90 Kg.), with hard nodular macules on the extensive surfaces of the elbows and knees. These vary in size up to as much as a centimeter in diameter. They are somewhat tender and painful on pressure. His physical examination is negative including a complete blood picture, urine analysis and examination of the teeth. The family history is negative. He is employed as a filling station attendant. Ordinary treatment has failed to give him any relief. Can you suggest a diagnosis and treatment?

M D Ohio

ANSWER—A macular formation is never nodular, having only two dimensions, so the query probably refers to a nodular formation. Nodules in the region of the knees and elbows may be due to various causes. Syphilis seems to have been ruled out in this case by negative blood examination. Certain arthritic conditions or gout may produce extra-articular nodules. Xanthomas are not always confined to tendons and their sheaths and may occur as extra-articular nodules. In rare instances, calcium is deposited in the superficial structures, but roentgen examination will disclose such formations. The most certain way to clear the diagnosis would be to perform a biopsy, removing one of the nodules and having it examined by a pathologist. Treatment must necessarily be based on the etiology.

SENSITIVITY TO MORPHINE—INDICATION FOR PITRESSIN

To the Editor—When a patient seems to be sensitive to morphine sulphate as evidenced by itching after a dose is given and is sensitive to barbiturates just what drug or combination of drugs can be given for postoperative relief of pain? Also what contraindications are there for the use of pitressin postoperatively for gas distention, especially in appendectomies? Please omit name.

M D, Iowa.

ANSWER—Codeine might be tolerated, as well as acetanilid and acetylsalicylic acid. A combination of these three drugs as in the following prescription might be synergistic:

J	Codeine phosphate	0.50 Gm.
	Acetanilid	1.00 Gm.
	Acetylsalicylic acid	4.00 Gm.

M and divide into fifteen capsules.
Label: One every hour until relieved or until three are taken then every two to four hours as required.

Pituitary might be of value in certain cases of adynamic ileus. It is contraindicated in intestinal obstruction, threatened perforation or the presence of a thin-walled intraperitoneal abscess.

PSORIASIS AND URINARY CALCULUS

To the Editor—I have a patient who suffers from psoriasis and who passed a ureteral calculus about one year ago. Is there any connection between the two ailments? Will you outline the present preventive measures to combat the recurrence of the calculus with emphasis on the diet? Kindly omit name.

M D Connecticut.

ANSWER—In all probability there is no connection between psoriasis and the development of stone in the urinary tract. The best preventive measures against recurrent calculus formation are:

- 1 The correction of any obstruction that may prevent good drainage from any part of the urinary tract.
- 2 Clearing up any infection.
- 3 Forcing of fluids.
- 4 Elimination of all foci of infection.

SPASMODIC TORTICOLLIS

To the Editor—A man aged 42 who has been employed as a laborer in an ice-making plant for four years developed a spasmodic torticollis. Can the daily exposure of cold—zero temperature—be explained as causal in possibly producing this condition? Please omit name.

M D Illinois

ANSWER—True spasmodic torticollis is characterized by clonic spasm of the various muscles of the neck, especially the sternomastoid and trapezius. The cause is some lesion of the nervous supply of the muscles, probably in most cases cortical. We have found no instance in which daily exposure to cold was considered an etiologic factor in producing this condition. Acute wry neck or rheumatic torticollis may be produced in susceptible individuals as the result of exposure to a cold draft of air.

VASECTOMY

To the Editor—In vasectomy should either or both ends of the cut vas be ligated and why? Please give accepted technique for the operation. Please omit name.

M D Colorado

ANSWER—In carrying out a vasectomy, both ends of the cut vas should be ligated, the lower end because testicular secretion would continue to be discharged from it and the upper end because it communicates directly with seminal vesicle and prostate and, should local infection occur, it might easily be carried to these organs. Again, if the ends are not tied they may grow together again.

Technic—Under infiltration anesthesia a small incision (15 cm in length) is made in the upper posterolateral wall of the scrotum, exposing the vas. Its sheath is dissected from it, a small section is removed and the cut ends are ligated and dropped back into the scrotum and the skin wound closed with one or two silk sutures.

ATROPINE IN COUGHS

To the Editor—I have been prescribing atropine sulphate in cases of chronic coughs in doses of 1/400 grain (0.00065 Gm.) once or twice a day. I also use it in cases of nervousness. Is the drug habit-forming? Would there be any untoward effects in using it over months—daily?

ALFRED JEFFERSON, M D Omaha.

ANSWER—Atropine sulphate is not known to be habit-forming and if it gives relief there is no objection to continuing it as long as desirable.

Illinois January Examination

The Illinois Department of Registration and Education reports the written and practical examination held in Chicago Jan. 22-24 1935. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Fifty candidates were examined, 49 of whom passed and one failed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Chicago Medical School (1933) 7*	(1934) 77 80 80 84 85 (1935) 77 79 79*	(1932)	81

Book Notices

The Problem of Mental Disorder. A Study Undertaken by the Committee on Psychiatric Investigations. National Research Council. Members of the Committee: Medison Bentley, Chairman, Sage Professor of Psychology, Cornell University; and E. V. Cowdry, Professor of Cytology, Washington University. This study was supported by a grant from the Carnegie Corporation. Cloth Price \$4. Pp 388. New York & London: McGraw Hill Book Company Inc. 1934.

Knowledge of mental disorders is extremely imperfect and the treatment of those who have mental disorders is correspondingly unsatisfactory. The authors attempt to take stock of the usable knowledge actually at hand and to discover how well the wide field of science, divested of professional and philosophic tradition, may supply new knowledge and new instruments of research. Five psychiatric points of view are presented by representative men in the various schools and branches of psychiatry: the clinical, the medical, the neurologic, the psychobiologic and the psychoanalytic. The supporting sciences to which the editors look with hope, are surveyed under the titles: problems in cerebral anatomy and physiology; electrophysiology of the brain; electrical measurement of activities in nerve and muscle; neurocytology; certain aspects of the chemistry and metabolism of the brain; neuropathology of the brain; the origin plan and operational modes of the nervous system; factors of neural integration and neural disorder; general biology and genetics; human constitution; endocrinology; the pathogenesis of neurocytotropic virus diseases; nutrition; pharmacology; general and experimental psychology; clinical psychology and the psychoneuroses; comparative psychopathology of infrahuman primates; psychotic symptoms and social backgrounds; cultural anthropology; and education. The volume is thus a collection of some twenty-five essays by so many authors. The plan of presenting the problem is commendable but almost too large for inclusion in a single volume, and the reader is annoyed by the sudden shifts starts and stops, for there is lacking the cohesion necessary to supply anything like unity. The style is spotty. A few of the essays are marred by the weight of the thoughts or the ponderosity of the diction, it is difficult to say which. The brevity of the more excellent essays is disappointing and frequently the stimulus to collateral reading is deflected by the absence of references. All told, there is much extremely valuable information enough to make one humble, and a little to make one hopeful. The book if read in its entirety, will be appreciated.

The Popular Practice of Fraud By T. Swann Harding. Cloth. Price \$2.50. Pp. 370. New York, London & Toronto: Longmans, Green & Company, 1935.

This book of Mr. Harding's covers much the same field as, and is a foil for, "100,000,000 Guinea Pigs" by Kallet and Schlink of Consumers' Research. The authors of both books are about as highly critical of the medical profession as they are of each other. Mr. Harding, in another place, has expressed the opinion that the American Medical Association is "not a scientific body, but a well-unionized trade guild determined to protect its own incompetent members and to increase the income of its supporters." While in his present book Mr. Harding is not quite so virulent against the American Medical Association, nevertheless this book, like "100,000,000 Guinea Pigs," details innumerable frauds, practically all of them of a medical character, and the material is based almost exclusively on the investigations made, paid for and published by the much damned American Medical Association.

The Popular Practice of Fraud is a book of 376 pages whose material could easily have been brought within the scope of 100 pages. It is endlessly repetitious. There is no index—which might have made it a convenient book of reference—and one wonders if the omission is intentional. Certainly an index would have emphasized its repetitious character. Each chapter contains many bibliographic references which the careless reader may not turn to. Such references, being designated simply by numbers in the body of the text, fail to bring home to the casual reader how impossible it would have been for Mr. Harding to write his book had the American Medical Association not done the enormous amount of work on medical frauds that it has in the past thirty years.

Unlike Messrs. Kallet and Schlink, Mr. Harding does not criticize the federal officials whose duty it is to protect the public against fraud in medical and other fields. For this he is to be complimented for the tirades against the Food and Drug Administration officials in "100,000,000 Guinea Pigs" were as undeserved as they were unfair.

Here and there Mr. Harding gives qualified and begrudging praise to the American Medical Association and its work. After criticizing the Council on Pharmacy and Chemistry for accepting certain products—which as further knowledge was developed, the Council later rejected—Mr. Harding says, "It is not contended that the Council can always be right. It is merely claimed that it operates under the somewhat onerous handicap of a considerable economic bias." Elsewhere he says, in dealing with the same general subject, "In general, acceptance by the councils of the American Medical Association is on a basis of scientific merit. There are notable and inexcusable exceptions but no such agency, Government or otherwise, can be perfect so long as human nature remains about what it is."

Toward the exploiters of the various frauds with which he deals, Mr. Harding's attitude is one of tolerance. He is apparently convinced that these persons are more sinned against than sinning and that their defections are due not so much to guile as to an imperfect economic system. This system, he says, "is subject periodically to catastrophic crises which render so many individuals and businesses insecure that fraud increases by leaps and bounds as efforts are made to survive the depression." He has no suggestion for another system and, indeed, questions whether it would not be a fact that "any other seemingly ideal system would almost certainly be accompanied by its own peculiar kind of imperfections."

In the closing chapter, entitled "The Future of Fraud," he states that "ruthless producers compete for suckers in a closed market, attacking with all the modern weapons of psychology, a public that completely lacks the elements of intelligent sales resistance." He then gives as an instance the case of "Listerine," and points out that the president of the Lambert Pharmaceutical Company has explained that when his company spent practically nothing for advertising, it earned only \$115,000 annually, but that when, in 1930, it spent approximately \$5,000,000 in advertising its net earnings after paying taxes, were considerably over \$7,000,000. Mr. Harding refers further to the various advertising claims made for Listerine as an alleged panacea for dandruff, halitosis and what-have-you and closes his references to this product by stating that when the

Listerine people decided to put out a tooth paste under the same name, the Listerine flavor had to be changed because the public would not accept it. Mr. Harding's reaction to the Listerine exploitation is "There is nothing heinous about it at all. The Company was merely doing what it felt compelled to do in a closely competitive profit economy where the public must be sold ever more goods. The selling is somewhat easier if people can be induced to believe that they are ill or that they can be protected from serious ailments by certain simple proprietaries."

We would not imply that the present book is not a valuable one. It is. Like Kallet and Schlink's "100,000,000 Guinea Pigs," it contains much valuable information and being written in an easy, easy style, will do much to awaken that large part of the public that Mr. Harding says "completely lacks the elements of intelligent sales resistance." And such an awakening is sadly needed. The pity is that the author, while finding the medical profession so necessary for furnishing him with most of the scientific data that his book contains, should feel constrained to belabor that profession so drastically. We believe that even Mr. Harding would admit that no other social group in the American scene has made such efforts to protect the public against fraud as is comparable with the work carried out at the expense of the organized medical profession of the United States in the medical field. Moreover, any honest judge of the medical profession of this country would admit that no other articulate group has ever been more critical of its own shortcomings or more ready to admit error when error has been committed.

Lehrbuch der Urologie und der chirurgischen Krankheiten der männlichen Geschlechtsorgane Von Professor Dr. Hans Wildbolz, chirurgischer Chefarzt am Hospital in Bern. Second edition. Paper. Price 64 marks. Pp. 616 with 218 illustrations. Berlin: Julius Springer, 1934.

This excellent work first appeared in 1924. After ten years it has been brought down to date in the present edition. Urology, always in evolution, is here presented in its latest aspect. The author, with the authority which his long and extensive experience gives him, has depicted his subject in a fully rounded and complete manner. As in the previous edition the divisions of the volume are devoted to general and special urologic subjects. Extensive attention has been paid to methods of examination, but for the most part the author omits theoretical discussions in order to make his treatise a practical work for the specialist as well as for the general practitioner. As a surgeon he was writing especially for surgeons, however, quite properly, a chapter on nephritis has been included. A discussion of gonorrhea and nongonorrheal urethritis also is noted. Wildbolz has merely touched on the new technique of transurethral prostatic resection. His own technique of perineal prostatectomy is fully described. The volume is clearly and coherently written and contains nothing but matter of importance. The references to the work of others are scanty and brief, but from the author's own rich fund of experience ample data are brought forth. The volume is well edited and beautifully printed. The illustrations are satisfactory. It can be recommended heartily as one of the best books on the subject in any language.

Anatomy for Dental Students. Systemic and Practical. By Six Teachers. Edited by E. P. Stibbe, F.R.C.S., Senior Demonstrator in Anatomy, London Hospital Medical School. Cloth. Price \$6. Pp. 429 with 216 illustrations. Baltimore: William Wood & Company, 1934.

The character of this book is clearly expressed in the first two sentences of the preface: "The purpose of this book is to present to dental students and practitioners as much of the subject of human anatomy as is necessary for their licentiate examinations and for reference after qualifying. It is often found impracticable in medical schools to provide completely separate courses for dental students in the ancillary subjects with the result that it is necessary for them laboriously to abstract from lectures and books those parts of the subject that are necessary to them, and even then they cannot be quite confident that they have covered just the right ground. This book frankly puts the book on the basis of a quiz compend to enable the student with the least effort and the least profit, to encounter successfully licensing examinations. This point of view is of questionable soundness. If a dental student should study fundamental medical sciences at all he should study them

from exactly the same point of view as the medical student. If a dentist is responsible for the diseases of the mouth, as an internist is responsible for the diseases of the liver, he requires the same basic training. The text covers well the limited scope of the book. Osteology is confined to the skull, the vertebral column and the bones of the limbs. One might ask at once "Why the bones of the limbs?" The study of joints is limited to the temporomandibular joint, the joints of the cervical spine and the joints of the clavicle. The only justification for this choice must be that the licensing examination in England is limited to these. The text is clearly written and, in view of its limitations, quite satisfactory. The author follows the classic error in describing the anterior belly of the digastric as the depressor of the mandible. The book is a limited presentation of a great subject from a limited point of view. For ready reference it is probably of considerable value.

Otitis rhino laryngologie du médecin praticien. Par le Dr Georges Laurene oto rhino laryngologiste de l'Hôpital Saint Joseph. Sixth edition. Paper. Price 42 francs. Pp 533 with 587 illustrations. Paris: Masson & Co 1934.

This is everything that a textbook for students and practitioners should be. The author never loses sight of the fact that he is not talking to the specialist. His attitude is that of the teacher who realizes that his reader wants facts and these he presents clearly and graphically. He takes nothing for granted but goes into minute details bearing on the fundamentals. The drawings accompanying the text cover every essential point from the manipulation of the head mirror to the minutiae of therapeutic procedures. A wealth of information is compressed within the pages in such a manner that the reader must be impressed with what the author believes he should know. Among the topics that are ordinarily given but little space in the average manual one finds deafness, tinnitus, vertigo, otalgia, epistaxis differential diagnosis of dyspnea, tracheotomy, vaccine therapy, dysphagia, and differential diagnosis of ulcerative lesions of the throat. The only criticism that might be offered is the omission of such topics as neutropenia and mononucleosis, petrositis and the use of contrast mediums in the diagnosis of sinus disease. The inclusion of these would have made the volume practically perfect.

The Adolescent in the Family. A Study of Personality Development in the Home Environment. Report of the Subcommittee on the Function of Home Activities in the Education of the Child. E. W. Burgess, Ph.D., Chairman. White House Conference on Child Health and Protection. Cloth. Price \$3. Pp 473. New York & London: D. Appleton Century Company, 1934.

Unlike many committee reports, this is not only a valuable collection of actual material but a readable report. Many of the facts established by the extensive surveys on which the report is based were known or generally suspected, but it is worth while to have them thus substantiated and assembled for the information of those whose work brings them in contact, and not infrequently in conflict, with the adolescent. On the whole, the American home seems not to deserve the severe condemnation so often meted out to it, on the other hand, there are many ways in which it could be bettered. Perhaps the most interesting of the conclusions from the report is the one which shows that the rural home, though externally appearing most solidly self contained, may in fact be less so than the city home which superficially gives the impression of being little if at all integrated as far as family life is concerned. The home seems to be of value to the adolescent practically without regard to its socio economic status: the deciding factors appear to be human relationships within the home. Neither does it appear that the only child is commonly believed, necessarily suffers in personality development solely by reason of being the only child quite the contrary may be the result. It all depends on the parents. The section of the report dealing with health is the least satisfactory. The authors in every section but this one have shown a commendable caution about letting their conclusions run away with their data but when it comes to health they naively present unverified data collected from children about the frequency of bathing and of brushing the teeth and ask the reader to accept them as criteria of the general health situation in the homes. An attempt is made to show a correlation between regularity in brushing the teeth and personality adjustment which would seem to be carrying the fetish of health habits to a new high in ridiculousness.

The section on health is so out of harmony with the general excellence of the book as a whole that one is tempted to do a little correlating of one's own and note that only two physicians were members of the subcommittee that sponsors this study. With this one exception, however, and in spite of it the book should be valuable to all who work with the adolescent—teachers, parents, social workers, ministers and leaders in youth movements. The recommendations of the subcommittee will be difficult to carry out, embodying as they do a number of suggestions for more parent education with respect to management of the child, and especially with respect to sex education, which is pointed out as the most glaring weakness of the modern American home.

La viruela y su profilaxia en Guatemala. Apuntes compilados por el Doctor Luis Galtan para presentarlos al segundo Congreso Centroamericano de Ciencias Médicas, que se reunirá en San José de Costa Rica en el mes de octubre de 1934. Paper. Pp 69 with illustrations. Guatemala: C. A. 1934.

Severe epidemics of variola have been recorded in medical annals of Guatemala during the last 300 years. From 1879 to 1881 smallpox swept over the entire republic, and in 1883 obligatory vaccination for all inhabitants of Guatemala was decreed. Vaccination is under the control of a sanitary commission. Since the institution of vaccination, the morbidity and mortality rate has decreased constantly and consistently. At the present time variola occurs only in sporadic form, and the actual number of persons suffering from this dread disease is small. These experiences are quite like those of other countries where widespread vaccination is the rule.

Miscellany

THE PRACTITIONER'S RESPONSIBILITY WHEN FUGITIVES ATTEMPT TO CONCEAL IDENTITY BY MEANS OF SURGERY

J. EDGAR HOOVER

Director, Federal Bureau of Investigation U. S. Department of Justice
WASHINGTON, D. C.

A postmortem examination of the body of John Dillinger disclosed that efforts had been made to alter the pattern appearing on the bulbs of his fingers, and that operations had been performed on his face in an effort to obscure his identity. That the effort to alter his facial appearance had proved unsuccessful was demonstrated when special agents of the Federal Bureau of Investigation, United States Department of Justice, recognized him instantly and brought his career to a close on encountering armed resistance from him at Chicago on July 22, 1934. That the attempt to mutilate his fingerprints was equally unsuccessful was shown by the fact that the bureau's fingerprint experts found 300 characteristics remaining in these patterns whereby Dillinger's identity could be conclusively established.

The attempts of Dillinger and other fugitives to change their fingerprints were occasioned by the knowledge that as long as telltale patterns remained on the tips of their fingers they could not hope to avoid the consequences of prior acts merely by adopting new aliases and changing their bases of operation. They realized that, no matter where they fled, the files of the Federal Bureau of Investigation would pursue them. How potent a force these files are may be judged by the fact that they contain almost 5,000,000 fingerprint records contributed by approximately 8,000 police agencies. An average of 2,800 fingerprint cards are added daily, almost half being of individuals shown by the records to have had a previous criminal history.

As a result of the increased use of fingerprint identification in the last decade, fugitives who in an earlier era after arrest on suspicion, might have been released because of the inability of the authorities to establish their true identity are now held

and turned over to the jurisdiction where they are wanted. Obviously, if some method could be devised whereby criminals could frustrate fingerprint evidence, they would subscribe to it eagerly.

It is not surprising, therefore, that criminals seek to enlist the aid of members of the medical profession whose knowledge and skill might enable them to obscure fingerprints and alter facial appearance. Although the attempt failed in Dillinger's case, and the physician who performed the operations was prosecuted, there is little reason to believe that the criminal element will relinquish the hope of utilizing the services of physicians and surgeons to conceal their identity.

Just what are a criminal's chances of successfully obliterating his identity through a resort to surgery? In the case of fingerprint mutilation while there may exist some difference of opinion as to the extent of the scars left as a result of such operations, the consensus of surgical experts seems to be that there would be definite delimitations in all cases. It is also evident that, when skin from other portions of the body is grafted to the finger tips, the ridge formations are different from those which customarily appear on the bulbs. The discovery by a police official of such a distinctly abnormal pattern would instantly place the official on guard and whether he could effect an immediate identification or not there is no doubt that the prisoner would be held in custody pending the determination of his identity.

The same consequences could be expected from burning or mangling the fingerprints. Of course, if the burns were less than third degree, the pattern temporarily effaced would again push itself to the surface. Assuming that rigorous treatment had destroyed all prints, the prisoner would invite the unremitting activity of police officials to determine who he was. In short, to tamper with the natural ridge formations of the finger tips would merely serve to obstruct and not to defeat identification.

No legitimate purpose can be imagined to account for a patient's application to a surgeon to have his fingerprints changed. To a law-abiding citizen it is a matter of indifference what pattern his prints follow. It is apparent, therefore, that the practitioner who undertakes to alter fingerprint patterns is lending himself to an attempt to defeat justice and violating the high ethical standards of the profession.

The position of the plastic surgeon consulted for changes in facial characteristics is somewhat different, in view of the fact that the patient may well be actuated by proper motives. The urge to improve on nature's handiwork is a common one, and many an upright citizen has been driven by the jeers of his fellow men to resort to surgery in the hope of achieving a more pleasing physiognomy. And whereas there is futility in fingerprint distortion, plastic surgery is capable of a marked degree of success in changing an individual's appearance, notwithstanding the failure of Dillinger's surgeon.

The resort to plastic surgery by the criminal element has, however, imposed definite responsibilities on the profession. With due consideration for the confidential relationship between doctor and patient, the surgeon should not permit himself to be used to further the ulterior motives of criminals seeking to evade apprehension. It has become increasingly incumbent on the plastic surgeon to scrutinize carefully the motives of patients in consulting him. The slight additional burden which this may impose is greatly outweighed by the public interest involved. And if the surgeon experiences the slightest misgiving in a specific instance, he should not become a party to the operation. Certainly, persons having legitimate motives for resorting to plastic surgery will not be greatly inconvenienced in properly identifying themselves.

It is of course evident that the most skilled and ethical practitioners will not further the aims of the criminal element.

Unfortunately, every profession has within it individuals who do not do credit to it and with whom the ethical members of the profession are at war. In any case falling within the jurisdiction of the Federal Bureau of Investigation, it promises full cooperation with the efforts of the medical profession to maintain high standards and will conduct vigorous investigation with the view to the prosecution of irresponsible practitioners who have assisted in altering the appearance of patients whose fugitive status is apparent.

Medicolegal

Contracts in Restraint of Medical Practice—The defendant sold to the plaintiff all of his office equipment, medical business and fixtures, including the good will of the business, and agreed that he would not for a period of five years thereafter open offices within the counties of Sutter or Yuba, California, for general or special practice of medicine or surgery. Within the time limit named, the defendant did open an office in the city of Marysville, county of Sutter, for the practice of medicine and surgery. In this action, the plaintiff sought to restrain the defendant from continuing in his practice contrary to his agreement. The trial court gave judgment for the plaintiff and the defendant appealed to the district court of appeal, third district, California.

The defendant admitted all the allegations of the complaint but claimed that his agreement not to practice was void under section 1673 of the Code of California. That section, and section 1674, pertain to contracts in restraint of trade, and read as follows:

1673 Every contract by which any one is restrained from exercising a lawful profession, trade, or business of any kind otherwise than is provided by the next two sections is to that extent void.

1674 One who sells a good will of a business may agree with the buyer to refrain from carrying on a similar business within a specified county, city or a part thereof so long as the buyer or any person deriving title to the good will from him, carries on a like business therein.

The defendant conceded that the word "business" in a general sense is broad enough to include any activity for profit or gain and therefore would include a profession, but contended that the legislature in stating the general rule in section 1673, *supra*, referred to "profession, trade, or business," whereas the exception as set forth in section 1674, *supra*, deliberately limited its effect to "business." However, said the district court of appeal, the Supreme Court of California in the case of *Ragsdale v. Nagle*, 106 Calif. 332, 39 P. 628, had the very same question before it and there held adversely to the defendant's contention. The court in that case said:

Section 1674 of the Civil Code says that one who sells the good will of a business may agree with the buyer to refrain from carrying on a similar business. It is now claimed that abstracting is not a business but a profession or trade and that therefore the provisions of the Code do not apply to the present case. It is sufficient to say the section is broad enough to bring the present case within its scope.

On the authority of the *Ragsdale* case, the district court of appeal affirmed the judgment in favor of the plaintiff—*Crutcheff v. Lacton (Calif.)*, 33 P. (2d) 839.

Workmen's Compensation Acts *Gonorrheal Ophthalmia Not Compensable*—The defendant in error, Elizabeth Hosafros, was employed in a cigar factory. She contracted gonorrheal ophthalmia, necessitating the removal of an eye. She attributed the infection to certain rags furnished by the employer, which were used by employees to wipe their hands and faces. After the industrial commission had denied her claim for compensation, she filed suit in the court of common pleas, where a verdict was rendered in her favor. The industrial commission carried the case to the court of appeals of Ohio, Hancock county.

There is no evidence, said the court, of any traumatic injury sustained by the employee. The undisputed testimony was to the effect that gonorrheal infection of the character under consideration is transmitted by direct contact of the secretion containing the germs with the mucous membrane of the eye. There

was no evidence that such infection is occasioned by or follows as a result of physical injury. As the disease from which the employee suffered was not occasioned by, or followed as a result of, a physical injury, it was not an injury within the meaning of the term as used in the workmen's compensation act of Ohio. Even if the infection had constituted an injury within the meaning of the compensation act, continued the court, the evidence failed to show that the employee contracted gonorrhea in the course of her employment. The evidence did show that the employee was not infected with gonococci elsewhere than in the eye. The court of appeals, therefore, held that the employee was not entitled to participate in the workmen's compensation fund, and the judgment of the trial court was reversed and judgment for the industrial commission entered.—*Industrial Commission of Ohio v Hosafros (Ohio)* 191 N E 832

Harrison Narcotic Act Administration of Narcotics as Constituting a Sale—The defendant-physician was indicted for a violation of the Harrison Narcotic Act to which indictment he demurred. In overruling the demurrer, the United States district court, W D Washington, N D, stated that from the facts incorporated in the indictment, which facts were not set forth in the printed report of the case the conclusion was inevitable that the relationship between the defendant and the recipient of the morphine was essentially that of seller and buyer rather than physician and patient. The recipient of the morphine procured and intended to procure that narcotic rather than the services of a physician, and, although the defendant was a physician, he not in the course of his professional practice nor in good faith nor for legitimate medicinal purposes, dispensed the morphine rather than legitimate professional services to the recipient. The indictment, continued the court, negatived the fact that the recipient may have been a patient of the defendant physician in the ordinary course of his medical practice. It was morphine that the recipient wanted and that the defendant was willing to dispense, rather than medical or professional attendance. Even though the morphine was in liquid form and its possession was changed from the defendant to the recipient by means of a hypodermic, it was none the less morphine that the defendant was delivering and the recipient was receiving, rather than essentially professional services. This transaction, concluded the court, comprised all essentials of a "sale" of the morphine.—*United States v Ratigan* 7 Fed Supp 491

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk () are abstracted below.

- Congenital Complete Heart Block with Labile Ventricular Rate. Case. H. D. Levine. Boston.—p. 376.

Pathology of Coronary Sclerosis.—Leary selected the material for his investigation from early lesions or from patients who had "dropped dead." This has permitted the study of the primary process uncomplicated by secondary reactions. The studies demonstrate that the standard lesion in coronary sclerosis is atherosclerosis and that the lesions arise from the entrance of lipoids into the subendothelial layer of the intima and their phagocytosis by cells that the author refers to as lipid cells. In the young the presence of these lipid cells stimulates growth of fibrous tissue. As a result, the standard picture in coronary disease in the young is fibrosis narrowing the lumen of the artery. Death is usually due to thrombosis. In the old the presence of lipid cells does not stimulate fibrosis. The cells accumulate in large masses, the nutrition of which becomes inadequate. Necrosis and autolysis result in liquefaction of the cell masses, and atheromatous "abscesses" result. Death is usually due to the rupture of an atheromatous "abscess" into the lumen. It is possible to reproduce the lesions of coronary sclerosis in experimental animals by feeding the lipid cholesterol, which makes up most of the lipid contents of atherosclerotic lesions. The lesions, natural and experimental, are primarily intimal and lipid. Lesions of the elastica and media are secondary. Inflammatory reactions are late phenomena following necrosis and are not an essential part of the picture. Atherosclerosis is a disease due to disturbances in the cholesterol metabolism and belongs with the other metabolic diseases, diabetes (carbohydrates), gout (purines) and obesity (fats).

Inversion of the T Wave.—In the course of routine electrocardiography, Graybiel and White occasionally observed inversion of the T wave in leads I or II of the electrocardiogram in persons who had shown no other clear evidence of heart disease. Because inversion of the T wave has been closely associated with serious myocardial disease, any exceptions deserve attention. Observations on neurocirculatory asthenia, a syndrome in which significant inversion of the T wave has not been reported heretofore, are described by the authors. The group consists of seven patients, three men and four women, with an average age of 24½ years. In not a single case was organic disease of any description found on repeated examination. The chief subjective symptoms were similar in all patients

and were induced by abnormally small effort. All complained of palpitation, six were easily fatigued, five complained of dyspnea and five suffered pain or ache in the region of the heart. All but two complained of nervousness, dizziness, faintness and excessive sweating were less common complaints. The size of the heart was not abnormal in a single instance. Heart rates were uniformly rapid and averaged 112 in the initial electrocardiograms. Murmurs were not heard in four, and an inconsequential systolic murmur was detected in three. The blood pressures of the patients were normal, as were the Wassermann reactions and basal metabolic rate determinations. At the time of the initial examination the electrocardiogram in each instance showed an upright T wave in lead I and an inverted T wave in leads II and III. No other electrocardiographic abnormalities were found. At the time of the last examination one patient was entirely well, five showed improvement, while one remained unchanged. None had developed organic disease, and the cardiac manifestations as observed clinically were not significantly altered except for the slower rates. Final electrocardiograms showed an upright T wave in leads I and II and an inverted T wave in lead III in each instance. This change in lead II was not associated with significant changes in the P or QRS waves. The heart rates, measured from the electrocardiograms, varied from 75 to 100, and the average was now 88. The authors also present four cases of thyrotoxicosis, five of infection, two of paroxysmal ventricular tachycardia and five miscellaneous cases in which an inversion of the T wave was observed but was not associated with usual known causes.

Circulatory Studies of Arteriovenous Aneurysm.—McGuire points out that the establishment of a large arteriovenous communication between the popliteal artery and vein in a healthy young man was accompanied by (1) an increase in systolic and a decrease in diastolic blood pressure levels, (2) cardiac and aortic dilatation and the symptoms of myocardial insufficiency, (3) dilatation and atrophy of the artery proximal to the arteriovenous communication and hypertrophy of the vein in the area contiguous to the fistula, an arterial aneurysm opposite the fistula, and (4) evidence of peripheral vascular malnutrition below the fistula, i. e. edema, ulceration of the skin, superficial varicosities, decrease in surface temperature and decreased pulsation of the dorsalis pedis and posterior tibial arteries. Digital occlusion of the fistulous communication produced (1) bradycardia and an immediate elevation of the diastolic and systolic arterial pressure, (2) definite elevation of the systemic venous pressure, i. e., antecubital vein, and (3) slight decrease in the size of the heart as seen fluoroscopically. Operative extirpation of the arteriovenous fistula caused (1) the disappearance of symptoms of myocardial insufficiency, (2) a marked decrease in the size of the heart, (3) after the initial rise a gradual drop in the systolic and a permanent rise in the diastolic arterial blood pressure to normal levels, and (4) diminution of peripheral edema in the affected leg, healing of the ulcers on the leg and the appearance of adequate arterial circulation in the foot.

New Active Principle in Ergot—Believing the commonly accepted idea that the physiologic activity of ergot resided in its alkaloids, Davis and his associates further separated the crude extract into an alkaloidal and a nonalkaloidal fraction. The residue that was almost free of alkaloids was exceedingly active when tested on the human uterus. The new active principle in its present form is agreeable and palatable. The dose is exceedingly small and may be dissolved in 3 cc or less of fluid. It produces no gastro intestinal or other undesirable symptoms in doses several times that required. It does not affect the pulse or blood pressure. When given orally the response is usually obtained in from six to fifteen minutes. Thus far the new principle has been tested on more than 100 postpartum patients in whom kymographic tracings of uterine activity were made for a period of three or four hours. The uterine motility initiated persists for three or four hours. It is characterized by marked and persistent uterine tone and frequent uterine contractions. The curve is one that may be characterized as a good ergot reaction. The usual methods of biologic assay were used to control the physiologic activity present in the new active principle. The best method of biologic assay for this new active principle is on the human postpartum uterus and on the postpartum uterus of the dog. The method of inserting a hydrostatic rubber bag for the study of uterine motility is entirely feasible in both cases.

Surgical Menopause After Hysterectomy—From a review of 2042 hysterectomies of various types, Kretschmar and Gardiner observed that hysterectomy with ovarian conservation in women 36 years of age or less was followed by menopausal symptoms before 40 years of age in 57.5 and 58.3 per cent for subtotal and total hysterectomy respectively. The greater delay in the occurrence of hot flashes after subtotal hysterectomy would suggest some endocrine function for the retained uterine tissue. Their study indicates that complete removal of all ovarian tissue hastens the onset but does not

shorten the duration of symptoms of the surgical menopause. The high incidence of menopausal symptoms following operations for pelvic inflammation would suggest that conservatism in this condition is unwise, if ovarian tissue showing degenerative changes is to be retained. The onset of the surgical menopause should not presuppose a decrease in or cessation of sexual activity, since 57 per cent of the patients who developed hot flashes showed either an increase or no change in their libido. A review of 1,022 patients with cervical cancer indicates that the condition occurs in the cervical stump after subtotal hysterectomy for benign causes in 176 per cent of cases. In 416 patients with previous subtotal hysterectomy who replied to a questionnaire one proved case of cervical cancer and five probable cases were found, an incidence of 1.44 per cent.

Amenorrhea Associated with Polycystic Ovaries—Stein and Leventhal report seven cases in which amenorrhea was associated with the presence of bilateral polycystic ovaries. Bilateral polycystic ovaries are most likely the result of hormone influences and not of inflammatory change. The diagnosis of ovarian pathologic changes is greatly facilitated by the use of pneumoventerography. The treatment of the amenorrhea with estrogenic hormone proved unsatisfactory. Surgical treatment consisting of wedge resection of the cystic cortex of the ovaries, was successful in completely restoring physiologic function. Menstruation in every instance became normal and remained so during the period of observation. Pregnancy followed in two instances. It is the authors' belief that a mechanical crowding of the cortex by the cysts interferes with the progress of the normal graafian follicles to the surface of the ovary. This mechanical factor may account for the symptoms of amenorrhea and sterility. Recurrence of the polycystic change in the ovary was not found in the follow-up examinations of any of the patients.

Ergot and Ergotamine Tartrate in Puerperal Prophylaxis—In a series of 169 consecutive parturients delivered under the same conditions, Der Brucke found that many had a mild elevation of temperature, not high enough to be put in the accepted morbidity group yet of sufficient persistence to make one realize that all was not quite well. In the group with the greatest number of cases of elevated temperature (53.15 per cent, the control group), lochia rubra persisted beyond normal duration, there was some form of lochia present at the time of discharge, and involution had not progressed as well in the multiparas as in the primiparas. The administration of ergot and more particularly its alkaloid, ergotamine tartrate prophylactically, hastened involution, lessened lochia rubra and checked lochial discharge by the tenth day.

Roentgen Study of Pulmonary Ventilation—Since Irawish wished to correlate the dimensions of the lung fields with the clinical determinations of pulmonary capacity requiring maximal ventilatory response of the individual, he selected maximal expiration and inspiration as the most desirable phases of respiration for roentgen study. He found a high degree of correlation between the area of the lung fields at maximal inspiration and the vital capacity of a person. This correlation has been improved by the use of the quantity roentgenologic chest volume which is obtained by multiplying the area of the lung fields at maximal inspiration by the thickness of the chest obtained by external measurements. Since the percental relationships of the subdivisions of the total capacity are constant the normal values of all the capacities may be predicted for any subject through the use of a regression formula. Comparison of the observed values of pulmonary capacity and its subdivisions with the predicted gives a reliable index of the degree of impairment in pulmonary ventilation the total variation in normal cases being less than 15 per cent. A fairly constant ratio has been found between the area of the lung field at maximal expiration and the area at maximal inspiration in normal persons. Restricted chest expansion is indicated by ratios varying by more than 7 per cent (men). These correlative tests have been found to be of value in differentiating those with disturbed pulmonary ventilation from the normal group.

Relationship Between Rheumatic and Subacute Bacterial Endocarditis—Von Glahn and Pappenheimer express the view that, in persons who have had rheumatism active rheumatic vegetations are a necessary and practically constant prerequisite for the implantation of the bacteria. They base this conclusion on the following evidence: 1 Vegetations histologically identical with those in rheumatic endocarditis and not

containing bacteria are found (1) on the same valve as the bacterial vegetations, (2) on other valves on which there are no vegetations containing bacteria and (3) on the auricular wall. 2 Aschoff bodies in the myocardium that are taken to indicate active rheumatic disease are found in practically the same proportion of cases of subacute bacterial endocarditis as of uncomplicated rheumatic cardiac disease. 3 Types of bacterial endocarditis other than that due to nonhemolytic streptococci may be engrafted on active rheumatic vegetations. This is a cogent argument against the view that the two types of lesions are a response of different intensity to the same infective agent, unless current views as to the histologic specificity of the rheumatic reaction are dispensed with. The authors do not claim that all cases of bacterial infection of the valves are the result of implantation on unhealed rheumatic lesions nor do they wish to deny the possibility that infection of the valve in cases of general sepsis may occur through the blood vessels of the valves. They have in their records several cases in which an acute interstitial valvulitis was unaccompanied by vegetations, indicating that the infection had reached the substance of the valve through the coronary circulation.

Sternal Marrow Aspirated During Life—Using a technique similar to Arunkin's Young and Osgood studied the marrow of twenty-eight healthy men and twenty-six patients. With the patient lying on his back, with his chest elevated by a pillow beneath his shoulders, the region of the sternomanubrial junction is prepared with iodine and alcohol. The skin, the subcutaneous tissues and the periosteum of the region are infiltrated with procaine hydrochloride. With an 18 gage spinal puncture needle from 3 to 4 cm in length, the sternomanubrial junction is entered in the midline at an angle of about 60 degrees to the surface of the chest. The needle is depressed to an angle of about 30 degrees and is forced not more than 1.5 cm into the marrow cavity of the body of the sternum. If much resistance is encountered the needle is rotated while pressure is maintained to facilitate penetration. The stylet is then removed and with a 2 cc Luer syringe 1 or 2 cc. of marrow is aspirated. If no marrow appears after strong aspiration, the stylet is replaced, the needle is inserted a little deeper and aspiration is done. The aspirated material, which looks like blood is transferred into a 4 by 1/2 inch (10 by 1.25 cm.) test tube containing from 2 to 4 mg of powdered potassium oxalate and shaken well to ensure mixing. The stylet is then replaced, the needle is withdrawn and the puncture wound is sealed with collodion. The oxalated marrow can be used for any type of hematologic examination that can be done on oxalated blood. Differential, peroxidase and reticulocyte counts were made on the oxalated marrow and on oxalated venous blood taken at about the same time. The results of the studies of the venous blood and sternal marrow of twenty-eight healthy male medical students show that the range of variation in the differential cell counts of the marrow was little greater than that of the blood. The results of studies of the marrow and blood in twenty-six cases representing fifteen different disorders of the blood and blood-forming organs are summarized. Study of the sternal marrow established the diagnosis of aplastic anemia and subleukemic monocytic leukemia, and it aided in the differential diagnosis of Banti's disease from Gaucher's disease, of anemia of congenital syphilis from aplastic anemia and aleukemic leukemia, and of multiple myeloma from a metastatic malignant process. Other problems that may be solved by this method are suggested.

Carbon Dioxide Content of Venous Plasma in Pernicious Anemia—Emerson and Helmer determined the hydrogen ion concentration and the carbon dioxide content of the venous plasma in twenty-nine patients with pernicious anemia and in sixteen normal persons. The results suggest that the condition of the acid-base equilibrium in pernicious anemia is independent of the clinical status and is essentially normal although there is an apparent tendency toward alkalosis and a deficit of alkali. Of possible significance is the variation of the pH over a range that was twice as broad in the patients with pernicious anemia as in the series of normal subjects. The daily administration of from 6 to 10 cc of a 10 per cent solution of hydrochloric acid produced no appreciable changes in the acid-base equilibrium of the blood in the patients with pernicious anemia.

Development and Treatment of Peptic Ulcer—Harper submits a method for producing an experimental peptic ulcer in a loop of intestine forming a fistula from an isolated gastric pouch to the abdominal wall. An ulcer formed in each of the dogs in which the fundus of the stomach was used in making the pouch. A combination of three factors was responsible for the development of these ulcers: the chemical and the mechanical factor and the factor of mucosal susceptibility. The chemical action of the gastric secretion was of prime importance. The increasing vulnerability of the intestinal mucosa to the formation of ulcer as the distance from the stomach increased was demonstrated. The mechanical factor probably played a part, for the ulcer developed at a point where the gastric secretion was held constantly in contact with the exposed intestinal mucosa. It was found that an ulcer in an isolated gastric pouch has the same effect in causing loss of appetite, vomiting and loss of weight as does an ulcer in the main gastro-intestinal tract. A preparation consisting of an emulsion of gelatin, acacia, olive oil and lecithin, introduced into the pouch twice daily, was effective in the healing of these experimental ulcers and prevented their formation. The pathologic changes that occurred in the healing of the ulcers were found to be similar to the changes that occur in peptic ulcers in man. The method of treatment brought out the fact that an ulcer will heal in about three weeks if its surface is adequately protected from the gastric secretion. The emulsion used in treating the ulcers has been considered only from the experimental point of view, and the authors draw no conclusion regarding its possible clinical application.

Neurofibroma of the Ureter—Ravich reports a case of neurofibroma of the ureter in which correct preoperative diagnosis of the tumor was made by means of a walled catheter and by a retrograde pyelogram. The erroneous impression of a concomitant pelvic tumor was created by the pelvic outline which showed an irregular mass in the lower portion of the renal pelvis. The case demonstrates the futility of the present day tendency among many physicians to depend entirely on intravenous pyelography for the diagnosis of all pathologic conditions of the urinary tract. There was freedom from symptoms until a short time before the operation in spite of the fact that the large tumor had been gradually increasing its encroachment on the ureteral lumen, with destruction of the kidney parenchyma. The success of early operation is apparent. The patient was alive and well in January 1934 when last heard from. The author states that the general practitioner should be as suspicious of vague urologic conditions as he is of a pathologic condition in the breast. It is only through early diagnosis and treatment that satisfactory results can be hoped for.

Staphylococcal Empyema and Pyopneumothorax—Neuhof and Berck believe that there are distinctive features in the pathogenesis, development and treatment of staphylococcal pulmonopleural suppuration. They describe the lesion in the form of empyema or pyopneumothorax as an entity and attempt to show that its consideration as such leads to more clearly defined therapeutic measures. The staphylococcus is the cause

of the great majority of suppurative pleural infections in infants. The pulmonary lesion from which the staphylococcal pleural infection is derived is usually an abscess of the lung. The invasion of the pleura is by rupture of the abscess in the majority of cases. A staphylococcal abscess of the lung with its complicating pleural infection is a metastatic lesion. The solitary abscess is analogous in origin and in pathologic process to carbuncle of the kidney and can be termed carbuncle of the lung. The authors describe four clinical groups: sacculated empyema, sacculated pyopneumothorax, total or subtotal empyema with or without mediastinal tension and total or subtotal pyopneumothorax with or without mediastinal tension. Communications with bronchi are present in the majority of cases in each group. The first two varieties, termed the adult type, present distinguishing pathologic features but are not distinctive clinically. The third and fourth varieties, termed the childhood type, are characterized by severe mechanical disturbances if there is tension on and shift of the mediastinum. The lesion requiring relief most urgently occurs with early rupture of the abscess of the lung in infants or in young children. The treatment of the adult type, rarely urgent, is by complete opening of the empyema through a liberal incision. The underlying abscess of the lung may require drainage. Urgent treatment is often imperative for the childhood type employing closed drainage.

Venous Carbon Dioxide in Pulmonary Disease—Richards and his associates investigated the applicability of the method of rebreathing for determining carbon dioxide tensions of the oxygenated mixed venous blood in certain cases.

of pulmonary disease. The method required the demonstration of the same "plateau" levels of carbon dioxide tension in successive rebreathing experiments, when the initial carbon dioxide tensions of the mixtures in the rebreathing bag in the separate experiments varied by several millimeters, and the demonstration of equilibrium between carbon dioxide tension in the samples of expired air (during rebreathing) and the carbon dioxide tension in the simultaneously drawn arterial blood. They found that the method gave satisfactory results in two cases of unilateral artificial pneumothorax and doubtful results in two cases of spontaneous pneumothorax with positive pleural pressures, and was unreliable in a case of advanced bilateral tuberculosis, a case of pulmonary fibrosis with dyspnea and two cases of advanced pulmonary emphysema. By the technique that the authors describe they can determine in a given case whether the method of rebreathing is applicable or not.

Phenylethylhydantoin Sickness—Rockwell made a controlled study of phenylethylhydantoin sickness in the hope that it might indicate how general are the changes in metabolism during fever and allergic states. He observed that in phenylethylhydantoin sickness, as in serum sickness, a temporary retention of water then of sodium and chloride, then of potassium occurred in the order stated. During the fever there was a slight tendency toward acidosis, as evidenced by a study of the acid-base equilibrium of the urine. At no time during the reaction did there appear any sign of alkalosis. The rate of oxygen consumption was increased in proportion to the height of the fever. The fuel for the increased heat production was not protein. The fever was relieved by an increase in the heat lost through the channels of radiation, conduction and convection.

Hemolytic Antibodies for Sheep Erythrocytes in Infectious Mononucleosis—Briley and Raffel state that the hemolytic and hemagglutinative antibodies for sheep and ox red cells found in the serums of cases of infectious mononucleosis are not heterophil or Forssman antibodies but are probably the specific response to an antigen having a factor in common with a thermostable component of sheep and ox erythrocytes, a certain strain of *Bacillus Welchii* and possibly horse kidney. These antibodies have the power not only to hemolyze and agglutinate sheep red cells but also to hemolyze and to some extent agglutinate ox red corpuscles, although these immune bodies are not isophil in nature since they are absorbed from the serum by boiled ox and sheep corpuscles. Ox erythrocytes have a broader antigenic relationship to the antibodies of infectious mononucleosis than sheep erythrocytes. The antibodies are probably not found in normal human serum but are rather a specific response associated only with infectious mononucleosis. These antibodies were not absorbed from the serum by any of the organisms cultivated from the upper respiratory tract of patients with the disease. Blood cultures made from cases of infectious mononucleosis were negative, although the injection into rabbits of such cultures containing the blood elements of a patient caused the production of a serum with a high hemolytic titer for sheep cells. The antibodies in infectious mononucleosis and the thermostable antigen in ox and sheep cells that combine with and neutralize them have unique properties of specificity. The primary titration of a serum with fresh sheep erythrocytes, followed by absorption of the antibodies with boiled ox red cells and then retitration of the absorbed serum with fresh sheep corpuscles, provides a specific diagnostic method for the disease.

Acute Hemolytic Streptococcus Infections—Tillet points out that a specific antisustance directed against the fibrin dissolving action of hemolytic streptococci was demonstrable in the blood of approximately 75 per cent of patients who recovered from acute streptococcal infections. The fibrin clot from the blood of patients who died of the infection was in no instance capable of inhibiting the bacterial fibrinolytic action. The antifibrinolytic response was demonstrable at the approximate time of recovery in some patients and was not detected in others until the second to the fourth week of convalescence. Generally the specific response appeared during the course of erysipelas earlier than it did following acute streptococcal infections of the upper respiratory tract. Twenty-eight patients

developed an antifibrinolytic resistance. All of them completely recovered and their convalescence was not interrupted by a reactivation of the infection. Seventeen patients failed to acquire humoral antifibrinolytic properties. In seven of these the disease was self-limiting and convalescence was uneventful. Of the remaining ten, seven died and three had prolonged illnesses due to exacerbations of active streptococcal infection. In the few cases of active rheumatic fever and acute nephritis that were studied, antifibrinolytic resistance was usually present. The response did not differ in its development from that which occurred in cases of acute streptococcal infection without the visceral disturbances of rheumatic fever or acute nephritis.

Clinical Spectroscopy—Gaul and Staud observed that the ultimate chemical and cellular disposition of lead in the body determines the distribution, localization and excretion. Its absorption may be either slowly accumulative or massive in character; the latter precipitating the signs and symptoms of an acute lead intoxication. It is the quantity of lead retained by the differentiated and undifferentiated mesodermic derivatives that causes the disabling sequels of plumbism. In the presence of a lowering *pH* or acidosis, the solubility of the retained lead is affected. This change in solubility will act like the unsheathing of a two edged sword, producing the signs and symptoms of acute lead poisoning; the severity of which will depend on the quantity of lead present and the degree of acidosis. In plumbism, signs and symptoms of excretion include all signs and symptoms referable to the mouth and the gastrointestinal, respiratory and genito-urinary tracts, and in retention all signs and symptoms referable to the central and peripheral nervous system and the muscular and skeletal systems. The excretion of lead is a favorable response. A plus designation is suitable for indicating the quantity or degree of lead retention. A biospectrometric analysis of cadaver biopsy specimens showed the lead line increasing in density in proportion to the age, with a mean lead retention of one plus. A biospectrometric analysis of six cases of plumbism showed a lead line the density of which indicated a three to four plus retention. A biospectrometric analysis of workmen in contact with lead showed a lead line the density of which indicated a one plus retention in 40 per cent of the group, a two plus in 28 per cent, a three plus in 12 per cent and a four plus in 20 per cent. A dermal biopsy specimen gives an accurate status of the quantity or degree of lead retention, whereas the blood specimen gives a false value for the degree of lead retention. The quantity of lead excreted in the urine and feces gives no indication of the quantity or degree of lead retention. The presence of basophilic stippling cannot be accepted as a diagnostic criterion or as a pathognomonic sign of plumbism.

Pleural Poudrage—Bethune believes that selective pleural symphysis without fluid formation can be produced as a preliminary to intrathoracic surgical operations such as lobectomy by using a fine commercial talc powder consisting of a 0.5 per cent iodized talc sterilized in the autoclave and introduced under local anesthesia in the sixth or seventh space scapular line through a thoracoscopic cannula with an air-tight valve. The pleura is inspected. The thoracoscope is taken out and the author's return air powder blower is inserted through the same cannula. Half a dozen puffs are given and then the thoracoscope is again inserted. This is repeated as often as necessary to cover the surface of the upper lobe. If the mediastinum is to be covered a longer cannula is used than the regular one, which projects only 0.5 cm beyond the tip of the thoracoscopic cannula. When the lung is covered so as to resemble a cake sprinkled with confectioners' sugar, the blower is detached and the air is completely aspirated. To make sure that all the air is aspirated, roentgen examination is indicated. If a line of pneumothorax is seen on the roentgenogram more than 0.5 cm in width this air must be extracted the same day. If less than this it may be left. Ten months has passed since operation was performed in the first of the author's five clinical cases and up to the present he has no reason to believe that ill effects are to be expected from the presence of this insoluble powder between the two pleural surfaces.

Cardiospasm Due to Diaphragmatic Gastric Hernia with Ulcer—Einhorn and his associates cite a case of cardiospasm that shows the great importance of a thorough roentgen examination for establishing the diagnosis and the value of surgery to effect a cure. The prominent symptoms of dysphagia of but short duration (three or four months) the absence of the swallowing sound at times alternating with its

delayed appearance at other times, and the constant presence of resistance to the passage of a bougie at about 15 inches from the teeth indicated cardiospasm probably due to a beginning neoplasm of the stomach. The duodenal bucket string test showing that there was no real stricture at the cardia or pylorus favored the same diagnosis. For this reason, duodenal alimentation had been instituted and the patient was greatly relieved temporarily. Bearing in mind the possibility of malignant changes the authors decided on another roentgen examination. This time roentgenograms revealed a diaphragmatic hernia as the probable cause of the cardiospasm. Etiologically a trauma (the lifting of a barrel) was probably the cause of the hernia. Surgery was successful and the patient thus far is apparently cured.

Prevention of Common Colds—Long discusses the value of various prophylactics that have been used for the prevention of the common cold. He has endeavored to determine the true part played by bacteria in the course of colds. He demonstrated that two main types of cellular response are found in the nasal secretions from patients with colds. One is characterized by an early predominance of phagocytic and epithelial cells in the secretions while in the other type polymorphonuclear neutrophilic leukocytes predominate from the beginning of the infection. Seven first day specimens of nasal secretions showed a predominance of polymorphonuclear neutrophilic leukocytes and four were practically free from bacteria when cultures were taken on blood agar plates while three contained thousands of microorganisms. Of eight first day samples of nasal secretions in which monocytes and epithelial cells predominated five showed an abundance of organisms and three were practically sterile. It is evident that on the first day of colds it is not possible to correlate the presence or absence of bacteria with a polymorphonuclear neutrophilic leukocyte response. As streptococci, staphylococci and pneumococci were the organisms generally found in these secretions this lack of correlation assumes added importance. After the fourth day the polymorphonuclear neutrophilic leukocytes averaged 90 per cent of the total cells present in the nasal secretions. Nevertheless a scanty bacterial growth was obtained from eighteen of sixty-five specimens examined in the late stages of these colds. The puriform character of the nasal secretions in the advanced stages of colds is not dependent on the presence of numbers of bacteria. The lack of correlation between the bacterial content and cellular response of the nasal secretions is

considered to be evidence of a lack of pathogeny on the part of these bacteria in the course of colds. Therefore it may be assumed that these organisms are present in the nasal secretions because these secretions constitute a medium favorable for bacterial growth. If true, the failure of bacterial vaccines to modify the severity or duration of uncomplicated colds can be easily understood.

Typhoid in Vaccinated Patients—Coburn and his associates observed thirty-nine cases of typhoid among vaccinated or partly vaccinated persons, from the study of which they conclude that 1 Typhoid vaccination furnishes relative, but not absolute protection against typhoid. 2 The incidence of typhoid in the vaccinated depends on the size of the dose of organisms swallowed. Their patients had undoubtedly ingested massive doses. 3 In the presence of suggestive symptoms typhoid should be considered even though the patient has been vaccinated. 4 Agglutination and protection from vaccination do not necessarily parallel each other. A positive Widal reaction may have diagnostic value even in a vaccinated person. 5 There is little or no difference clinically between typhoid in the vaccinated and the nonvaccinated. 6 Mortality may be lower in the vaccinated especially in the recently vaccinated but variations in virulence in different epidemics must not be overlooked. 7 A high incidence of relapses may be associated with high caloric feeding.

*Observations on Arsphenamine Dermatitis with Especial Reference to the Reliability of the Patch Test J W Jordan and E D Osborne Buffalo—p 210

Finding Tubercle Bacilli J S Woolley I oannis—p 217

Arsphenamine Dermatitis—Jordan and Osborne state that the patch test is not a reliable guide to further treatment with the arsphenamines following recovery from an arsphenamine dermatitis. Patch tests may be negative or only slightly positive when cutaneous intolerance to the further intravenous administration of the drugs exists. Severe vesicular forms of dermatitis following the intravenous administration of the arsphenamines appear to represent true allergic reactions to the arsphenamines or to products of their metabolism. Further treatment is usually contraindicated. Mild erythematous and erythematopapular forms of arsphenamine dermatitis do not

appear to represent true allergy to the arsphenamines or products of their metabolism and usually do not contraindicate further treatment with these drugs. On the basis of their observations and those of others, the authors suggest that patch tests with the arsphenamines may induce a state of cutaneous allergy where none existed previously. They believe that, in the present state of knowledge, the only safe method of determining whether further arsphenamines can be tolerated following a mild arsphenamine dermatitis is by the intravenous administration of small gradually ascending doses of arsphenamine.

Foreign Body in Middle Metatarsal Bone C R Kessel, Ripley—p 123

Perineal Hernia Case Report W W Strange Huntington—p 125

Use of Dextrose in Heart Disease—Podolsky says that dextrose has two definite modes of action on the heart. The first is its angiotrophic action, which is of particular value in angina pectoris and coronary sclerosis. The second is that the administration of large amounts of sugar permits of glycogen storage both in skeletal and in heart muscles. Intravenous injections of dextrose can be given safely and with little reaction if proper precautions are observed. The strength of the solutions used varies from 5 to 50 per cent. The amounts given may vary from 5 cc per kilogram of body weight in the case of concentrated solutions to 20 cc per kilogram in the case of more dilute solutions. Intramuscular injections of dextrose may be given with safety by observing the same precautions as with intravenous technique. Subcutaneous injections of 10 per cent may be given with safety. In the experience of Rimbraud Balmes and Anselme Martin, dextrose-insulin therapy has yielded excellent results in cases of cardiac failure particularly in the reduction of edema and the relief of subjective symptoms. Left ventricular insufficiency is generally influenced favorably under insulin-dextrose treatment, with an improvement in the quality of the auscultated sounds. Dextrose-insulin therapy is most likely to succeed in the early stages of cardiac insufficiency before gross anatomic changes have been suffered by the myocardium. Insulin acts directly on the nutrition of the myocardium and also produces an equilibrium of the two functions of glycolysis and glycogenesis. Insulin-dextrose therapy in heart disease is not wholly free from danger. Quite a few cases of stenocardial pain following the administration of insulin have been reported particularly in patients suffering from arteriosclerosis. Occasionally coronary occlusion may follow as a result of insulin therapy. In a heart already impoverished by coronary disease, the injudicious use of insulin alone metabolizes too much glycogen, an element of great importance in myocardial tissue metabolism, and leads to further physiologic imbalance. The most unfavorable results with dextrose-insulin therapy occur most often in diabetic patients, in whom the heart is already adjusted to high sugar levels. The introduction of insulin therapy suddenly reduces this level with resultant cardiac pain. Dextrose is also not to be thought of as a heart remedy in these cases. Experimental evidence shows that the heart muscle gives up its glycogen with great difficulty, and yet this change is influenced to a great degree by quite a few endocrine substances, particularly epinephrine, thyroxine, solution of pituitary and insulin. While these substances may produce only minor changes in a normal heart, they may bring about rather undesirable alterations in a heart that is diseased. This may be the case in diabetes as well as in arteriosclerosis. It is desirable to make a thorough examination of the patient before dextrose or dextrose-insulin treatment is instituted in heart disease.

Obsessive Compulsive States in Childhood and Their Treatment. Muriel Barton Hall.—p 49

Papular Urticaria—Tate concludes that papular urticaria is a definite and distinct syndrome, separable from urticaria and from Hebra's prurigo. It is a manifestation of allergy and a disorder of the first four years of life. It is aggravated by heat and by a diet containing too much carbohydrate. Digestive disorders, teething and mild febrile disturbances probably predispose to papular urticaria, but such conditions are of minor importance in its etiology. Rickets plays no part. There is no satisfactory evidence of any underlying diathesis. The exciting agent is not a food but something connected with the patients' home environment. Its precise nature however remains obscure. It is not bedding or clothes but it can be carried on these articles. It is not vermin, animal size, or an antigen derived from human beings or domestic animals. Sensitivity to house dust has not been definitely excluded. Many children suffer from transient attacks of papular urticaria and recover without treatment, an important fact that must always be borne in mind in any attempt to estimate the value of a particular remedy. Treatment is tested by the chronic cases and only too frequently it proves far from satisfactory. The admission of the patients to a hospital always brings relief, and in the author's cases, although relapse occurred when they returned home the symptoms were much less severe than before. This seems to be by far the most valuable therapeutic measure in all those severe and persistent cases in which the general health suffers from the continual irritation and loss of sleep.

Species Immunity to Pneumococcus—The experiments of Harley demonstrate that when solutions of pneumococcus type specific antigens (prepared by allowing pneumococci to undergo partial autolysis in acid sodium chloride or by extracting the organisms with dilute acid at 60 C.) are rendered alkaline and incubated at 37 C. the immunizing properties of the solution for mice are altered. The injection of pneumococcus type-specific antigen solutions or of heat-killed vaccines in mice produces an immunity only to the homologous type of organism. The injection in mice of solutions of type specific antigen solutions that have been made alkaline and incubated at 37 C. produces an immunity not only to the homologous type of organism but also to the heterologous types. It seems probable that this change of antigenic properties is due to an alteration in structure of the type-specific antigen possibly of the nature

of a hydrolysis. The author states that the foregoing experiments confirm the work of Day that pneumococcus species antigen preparations produce in mice an immunity to virulent pneumococci generally.

Streptococcus Complement Fixation Reaction in Rheumatic Diseases—Beck and Coste made complement fixation tests on seventy-nine serums from rheumatic patients and on fifty-three control serums. A number of the former group gave positive reactions with streptococcus lipid antigens and failed to react with lipid antigens of other bacteria or with tuberculous and syphilitic lipid antigens. Examinations of the control serums showed that tuberculous serums and serums of pregnancy often react with streptococcus lipid antigens. Therefore in assessing the significance of positive streptococcus reactions these conditions must be excluded. The positive reaction with a streptococcus antigen has been observed only in cases of rheumatic disease in which clinically a connection with streptococcal infection was probable. But even in these cases, and also in acute streptococcal infections (scarlet fever, erysipelas) the proportion of positive reactions is not high (seven positive reactions out of forty-four rheumatic serums). The authors think that the sensitiveness of the reaction is not yet optimal and they are now trying to increase it. If this can be done it may be possible to determine whether rheumatic disease is of streptococcus or other origin.

Action of Acetone and of Ketone Bodies on the Heart—Bagoury compares the action of acetone, of beta-oxylbutyric acid and of diacetic acid on the heart muscle and on the coronary circulation. The substances to be tested were administered singly or together in various proportions, and in some experiments the concentration of the blood sugar was raised in order to imitate the diabetic conditions. The ketone bodies and the sugar were used in concentrations reported to be present in mild and severe forms of diabetes, and also in concentrations considerably above those found in human diabetes. Acetone and diacetic acid produce a weakening of the heart as evidenced by cardiac dilatation and rise of the venous and pulmonary pressures. The toxicity of diacetic acid is from about fifteen to twenty times greater than that of acetone. The minimal effective concentration of diacetic acid is from 2 to 3 mg. per hundred cubic centimeters and that of acetone from 25 to 40 mg. The weakening effect of acetone remains unchanged so long as the acetone remains in the circulation. When the blood is replaced by acetone-free blood, the heart recovers completely. The cardiac dilatation produced by small doses of diacetic acid tends to disappear spontaneously. Beta-oxylbutyric acid has no specific action on the heart up to concentrations of 1 per cent. Its effects are entirely accounted for by the change in the acid-base equilibrium that the acid produces in the blood. The three ketone bodies produce an increase in the coronary flow of the blood. This effect is, however, negligible unless the concentration of these substances in the blood is high.

*Luminescent Properties of Zinc Sulphide in Relation to \ Rays. L Levy and D W West.—p 184

Luminescent Properties of Zinc Sulphide in Relation to X-Rays—Levy and West point out that the fluorescent and phosphorescent effects of zinc sulphide when stimulated by many types of radiations are in most cases more intense than similar phenomena displayed by any other known substance. Zinc sulphide has never found practical application in roentgenography owing to the phosphorescence that heretofore has always accompanied the fluorescent phenomena. Entirely new types of zinc sulphide have recently been developed, which exhibit intense fluorescent effects without any phosphorescence. The application of these substances to roentgenography has resulted in considerable improvements in fluorescent screens for visual purposes and also in intensifying screens, special varieties of which have found application in roentgen cinematography.

raphy The response of these new fluorescent substances toward the softer radiations is greater than that shown by the substances previously in use This enables roentgenographic work to be carried out with advantage at a lower kilovoltage than that which was formerly employed The new zinc sulphide intensifying screens have also found application in reducing the long exposures heretofore required for roentgen spectroscopy The exposure is reduced in certain cases to one twentieth of the normal value The latent image of roentgen exposure can be stored in the phosphorescent type of zinc sulphide and rendered visible to the eye for subsequent examination

Basophil Adenoma of the Pituitary with Renal Changes—Close cites the case of a basophil adenoma of the pituitary in a male identified by necropsy Apart from the high blood pressure there was no reason to suspect either the syndrome or the pituitary lesion and the finding of the basophil adenoma was accidental The case is unlike the others of basophil adenoma so far recorded in that the kidney was markedly affected by chronic glomerulonephritis But there was no evidence to suggest that the association of the chronic glomerulonephritis with the basophil adenoma or with the malignant hypertension was other than fortuitous Liability to sepsis was exemplified in the present case The patient had had many sore throats in the last eight years of his life, and at the postmortem examination the foul condition of the tonsils was a striking feature The author does not consider abnormal the absence of cells in the posterior lobe of the pituitary in spite of Cushing's recent attempts to attribute the raised blood pressure to the secretion of these cells The author states that if a large series of pituitaries are examined it will be found that the invasion of the posterior lobe by cells growing out from the pars intermedia is comparatively common particularly in middle aged subjects, and that marked invasion of the posterior lobe may also be seen in the pituitaries of persons whose blood pressures have been normal for at least several months before death

Meningeal Tuberculosis—Macgregor and her associates give the following tentative conclusions regarding meningeal tuberculosis 1 Tubercle bacilli may be present in the cerebrospinal fluid in the absence of diffuse tuberculous meningitis 2 Diffuse tuberculous meningitis is usually the result of infection of the subarachnoid space from a preexistent localized focus in the brain or meninges, not a direct result of miliary tuber-

culosis 3 Such localized foci result from infection of the central nervous system by numbers of tubercle bacilli, too small to produce diffuse meningitis, taking place during periods of bacillemia 4 Such limited infections, giving rise to localized lesions, sometimes occasion clinical manifestations of a pathologic process within the central nervous system, which may be transient and from which clinical recovery may be complete at least for a time

Renal Tuberculosis—Band states that the earliest tuberculous lesions of the kidney are epithelioid and mononuclear tubercles They are found in relation to the glomeruli of the renal cortex These primary or minor tuberculous lesions of the kidney are bilateral Many of them heal The presence of tubercle bacilli in the urine withdrawn from the renal pelvis means a tuberculous focus in the kidney Early tuberculous follicles may become encysted and fail to discharge infected debris to the tubules, i e, remain closed As a rule, caseating foci ultimately ulcerate to the tubules The collecting tubules converge at the apex of the pyramid, which is thus liable to infection by direct spread from foci in the corticomedullary zone and by tubular extension A lesion is open when it communicates with the renal pelvis either directly or through the tubules The presence of open cortical lesions can be diagnosed clinically when tubercle bacilli and pus cells are found in the renal urine and changes in the pyelographic outline of the renal pelvis and calices are absent The later stage of confluence of follicles and ulceration at the papilla leads to the pyelographic changes and the clinical syndrome of tuberculous disease of the kidney

*Secondary Marble Bones F P Weber—p 377

Treatment of Parathyroid Tetany—Campbell reports two cases of parathyroid tetany in which there was complete achlorhydria No examination of the gastric juice had been made before operation, so that it is impossible to say whether this achlorhydria was a result of the removal of the parathyroids The severity of the symptoms depended not only on the actual content of the serum calcium but on slight shifts in the level The symptoms seen for example when the serum

calcium was 7 mg per hundred cubic centimeters and rising from a lower level were often much less than those exhibited when the serum calcium was between 8 and 9 mg and falling. The author asserts that a good method of treatment is to present continuously to the intestine a large amount of calcium in the form of calcium chloride (150 grains, or 9.75 Gm daily). This may be all that is required. But in cases in which this is not effective, and especially if achlorhydria is present, from 50 to 100 cc of third normal hydrochloric acid should be given to increase the absorption of calcium. The acid is added to milk in the proportion of 1:20, when a curdled acid-tasting mixture is formed, which is pleasant enough to take.

Basophil Adenoma of the Pituitary Body—Swan and Stephenson describe the case of a woman aged 30, who for four years had suffered from abdominal obesity, hirsutism and long periods of amenorrhea. The blood pressure was raised. Death occurred suddenly during an attack of pain probably renal colic nine days after a copious hematemeses. At necropsy the principal macroscopic changes were obesity, calculous pyonephrosis, cholelithiasis, acute gastric ulcer and enlargement of the anterior lobe of the pituitary body. Microscopically nearly the whole of the anterior lobe of the pituitary body consisted of an adenoma of the basophilic cells. The adrenals showed hypertrophy of the cortex. Renal changes were slight. There was evidence of osteoporosis.

Secondary Marble Bones—Weber designates as osteoplastic reaction the profuse dissemination into the bones in some cases of primary prostatic carcinoma. The bones become infiltrated by millions of minute metastases, mostly smaller than milium, many consisting of only a few cancer cells at the time of the patient's death. In such cases the disseminated cancer cells may excite a remarkable osteoplastic reaction, which causes the infiltrated bones to increase in density (carcinomatous osteosclerosis) by formation of new bone and deposition of bone salts. Roentgen examination in extreme examples shows the medullary cavity to be more or less obliterated and from this point of view he suggests that the condition may be termed secondary or carcinomatous marble bones, in contradistinction to primary marble bones—a developmental abnormality also called osteopetrosis or the Albers-Schönberg disease. He explains the cause of the remarkable osteoplastic reaction in the infiltrated bones in the following manner. The prostatic epithelium, if transplanted, would probably exert an osteogenic influence similar to that which has been experimentally demonstrated in the transplanted epithelium of the urinary bladder, ureter and renal pelvis by Huggins and others. It is generally recognized that cancer cells often retain some of the vital qualities peculiar to the cells from which they arise and it is not too much to suppose that the cancer cells in some cases of primary prostatic carcinoma still retain osteogenic properties—sufficient to give rise to hyperplastic osteosclerosis in the bones which they infiltrate. This would account for the fact that a hyperplastic osteosclerosis occurs far less frequently in association with cancerous metastases in bone from sources other than a prostatic carcinoma.

Homogeneous X Radiation in Biologic Experiments

—According to Eddy, since the intensity in any small wavelength range is always only a small portion of the total intensity of the x-ray beam it is inevitable that any method of selecting a narrow band of wavelengths must give a beam of feeble intensity. It is desirable, therefore to use x-ray tubes especially designed to operate continuously with large currents. When the wavelength range required includes the characteristic lines of an element it is an advantage if possible to use that element

as the target material. If the wavelength range is to be selected by means of a crystal, special care should be taken to exclude scattered radiation from the selecting slit, and the voltage should not exceed that necessary to excite second order radiation. If, in order to obtain beams of greater intensity wide slits are used, the wavelength range of the selected beam is increased considerably. The only satisfactory method of determining the homogeneity of such a beam is by analysis with a suitably designed crystal spectrograph. If the filtration method of selecting a wavelength range is adopted, the necessary filter thickness can be calculated readily. The value of the voltage to be used should also be carefully selected in relation to the filter thickness, as the use of too high a voltage for any given filter thickness seriously affects the homogeneity of the beam. If a narrow range of wavelengths is to be used for biologic experiments in which a specific action with wavelength is suspected, it appears desirable that the actual range of wavelengths as well as the distribution of energy within that range should be determined. The success of a physical-biologic experiment can depend only on the success with which both the physical and the biologic portions have been planned.

Treatment of Pernicious Anemia—Wilkinson points out that the fundamental principles underlying the successful treatment of pernicious anemia imply the realization that the condition is a permanent deficiency disease requiring adequate replacement therapy for life. Treatment consists in the administration of one or more of the antianemic factors present in the stomach or liver, but they must be given in sufficiently large amount to maintain a normal blood picture and clinical condition. This can succeed only if therapeutically active preparations are used. The progress of the patient must be controlled by regular blood counts at least every three or six months, and the dose of antianemic treatment increased or decreased accordingly. If there are any signs or symptoms however slight, of involvement of the nervous system, the treatment must be continued in full doses without relaxation. The prognosis in uncomplicated cases of pernicious anemia is good provided these points are borne in mind and adequate treatment with an active preparation is taken for the rest of the patient's life.

Anemia Associated with Splenomegaly in Childhood

—According to Ellis, the investigation of an infant or child suffering from anemia and splenomegaly will first necessitate the exclusion of a generalized infection. A clinical diagnosis of congenital syphilis or miliary tuberculosis will be confirmed by the Wassermann reaction or the Mantoux test, although the latter may be negative in the terminal stages of a generalized infection. A history and temperature suggestive of septicemia should call for a blood culture and, whenever the diseases are endemic, infantile malaria or kala azar should be suspected in any doubtful case and the blood or material from a splenic puncture should be examined for parasites. In any severe anemia whether primary or secondary transfusion may be required to save life and will frequently hasten recovery in the milder cases. Splenectomy is indicated in acholuric family jaundice in Bant's disease and in splenic anemia when the platelets are reduced and in severe anemia secondary to hemorrhagic purpura (thrombocytopenic purpura). In general, iron may be expected to benefit only those cases of anemia which form the great majority in childhood and in which there is an iron deficiency although recent work suggests that some benefit may be obtained from iron therapy in true splenic anemia.

Tuberculous Antecedents in Polyarthritides—Coste and his co-workers studied the antecedents of 184 patients suffering from polyarthritides and 329 nontuberculous patients in order to determine the percentages of each exposed to the tubercle bacillus. They were classified in three groups (1) subjects definitely exposed to personal or familial tuberculosis or having lived in prolonged tuberculous contact, (2) those for whom these conditions perhaps existed and (3) those without tuberculous antecedents. Of the 184 polyarthritic patients 30.6 per cent were in the first group, 25.7 in the second and 44.2 in the third. Of the 329 other nontuberculous patients 12.1 per cent were in the first group, 10.6 in the second and 77.2 in the third. There was thus a significantly higher percentage of polyarthritic patients exposed to tuberculosis than of the other patients. Although the number of patients was small the authors believe that these observations should stimulate further studies of the possible relationship between tuberculosis and chronic polyarthritides.

- *Place of Phlebitis in Early Spontaneous Postoperative Evisceration J Duening —p 281
- *Prophylaxis of Accidents Due to Neosarsphenamine J Benet —p 283
- Serous Meningitis of Poliomyelitis and Tuberculous Meningitis B Tassovatz —p 285

Phlebitis in Postoperative Evisceration—Duening reports five cases of postoperative evisceration occurring relatively soon after the operation. In four of these phlebitis had taken place. In three the preceding phlebitis of the pelvic abdominal region had produced distention of the abdomen and urinary difficulties. The mechanism of evisceration in these cases is easy to explain on the basis of increased and constant traction on the sutures closing the abdominal wall. He does not believe that phlebitis is by any means the only cause of postoperative evisceration but feels that it is often more than coincidental.

Prophylaxis of Accidents Due to Neosarsphenamine—The frequent toxic effects caused by the administration of neosarsphenamine induced Benet to investigate preventive methods. He prepared ampules containing 5 cc of a 4 per cent solution of aminoacetic acid as a diluent. One ampule suffices for doses of neosarsphenamine up to 0.75 Gm and two ampules are used for larger doses. In one period of three months he treated twenty women more or less intolerant to the arsphenamines. One hundred and eight injections were given with this product. In sixteen cases the results were entirely and in four partially satisfactory. The explanation for these good results is still uncertain. It is possible that a solution of an amino acid is merely a better solvent than distilled water. Perhaps aminoacetic acid has a stimulating action on the antitoxic function of the liver. The author believes that this is the most likely explanation. It is also possible that aminoacetic acid acts directly on the metal and reduces its toxic properties. Whatever the explanation it is certain that the results are good.

- *Mechanism of Action of Autohemotherapy in Cerebral Hemorrhage G Rabboni and S E Gurrieri —p 153
- Primary Sarcoma of Stomach Cases F Guccione —p 168

Hemorrhagic Syndromes and Anemia in True Chronic Uremia—Gualdi studied the pathogenesis of the hemorrhagic syndromes and grave anemia in true chronic uremia. The toxic

stage of true chronic uremia is characterized by humoral changes of a physicochemical nature, which originate essentially in the complete insufficiency of the kidney and partially in the insufficiency of the liver and cause, on the one hand, functional and histologic alterations of the bone marrow resulting in the development of grave anemia and, on the other, diffuse lesions of the capillaries resulting in the production of the hemorrhagic diathesis. The statement of the author is confirmed by clinical observations. Grave anemia and either cutaneous or mucous hemorrhages were seen in patients suffering from true chronic uremia secondary to renal insufficiency and did not appear in patients suffering from grave renal diseases but without true chronic uremia.

Autohemotherapy in Cerebral Hemorrhage—Rabboni and Gurrieri determined the hemolytic power of the blood serum of sixteen hemiplegic patients before and after autohemotherapy. The presence of hemolysins and hemoagglutinins before autohemotherapy in more than one third of the samples of serums and the appearance or increase of the same substances after autohemotherapy in about half the samples of the same serums led the author to believe that the mechanism of action of autohemotherapy in cerebral hemorrhage is of an immunobiological nature. The blood, on being re injected, acts as a globular antigen resulting in the formation or the increase of hemolytic antibodies that reinforce the spontaneous globular lysis in the cerebral hemorrhagic foci and accelerate the reabsorption of the hemorrhage. It causes also humoral colloid modifications by which the equilibrium of the cerebral circulation is reestablished. A relation between the intensity of the hemolysis and the results of the treatment is not clear, although it seems to exist between the intensity of hemoagglutinins and the results of the treatment. In the course of their studies the authors had the opportunity of confirming the reports of Colella and Pizzillo on the satisfactory results of autohemotherapy in hemiplegia even in those forms that represent late results of cerebral hemorrhage. Seven hemiplegic patients out of a group of twelve who received the complete treatment long after the apoplectic attack occurred showed satisfactory results.

- Phlebitis and Postoperative Embolism and Their Prophylaxis. A Parini —p 223

Extract of Urine and the Diagnosis of Cancer—Negri applied the biologic urine test of Aron for the diagnosis of cancer in ten patients. The test consists in adding in a large flask a quantity of freshly passed urine from suspected patients to three times its volume of 95 per cent alcohol. After shaking a precipitate forms and settles slowly. After the sedimentation is completed the supernatant fluid is decanted. The remaining material is centrifugated. The precipitate is suspended in from 5 to 10 cc. of physiologic solution of sodium chloride for each hundred cubic centimeters of urine and the suspension is violently shaken for a long time. After filtration the active principle is found in the filtrate, to which is added a few drops of a 3 per cent solution of trisecol and which is kept in the refrigerator. The filtrate is injected subcutaneously in rabbits weighing from 1,500 to 2,000 Gm. It is advisable to administer to the animals the solution of the precipitate corresponding to from 750 to 1,000 cc of urine. The injections are repeated for two or three days at least. Necropsy is performed two days after the last injection. The adrenals of the rabbits treated are removed, dissected and fixed for several hours in Zenker's solution formalized 7-100. Sections from 5 to 6 microns in thickness are cut and stained with an erythrosin stain. The author's results do not confirm those of Aron. According to the latter the reaction is positive when the spongocytes of the fasciculated zone of the adrenal cortex lose their lipid granulations and are stained so that the normally clear fasciculated zone becomes obscure, not one of the author's positive cases gave these results. The fasciculated

zone always presented a normal aspect with the cellular nucleus visible and finely reticulated protoplasm, vacuolated as much in rabbits treated with urine from cancerous patients as in the controls. The numerous histologic sections made of the hypophysis did not demonstrate the presence of pathologic processes in any of the animals. The only alteration that the author found in the reticular zone of the adrenal cortex was a degenerative process of the cells. This condition was established by seven of eight specimens of urine from patients with malignant disease. The author concludes that the injection of urinary extract according to Aron cannot be used as a means of excluding or confirming the possible presence of a malignant disease. The histologic changes that the treatment produces in the adrenal cortex are not sufficiently marked. The tests did not show any change in the fasciculated area but rather a degenerative process of cellular elements of the cortical reticular zone.

- *Total and Subtotal Thyroidectomy in Treatment of Heart Diseases and of Angina Pectoris G Bankoff —p 590

Neuralgia of Amputation Stump—The concept that neuralgias of the amputation stump are due principally to a neuroma of the larger nerve trunks such as the sciatic, median ulnar or radial, is not borne out by Molotkoff's investigations. The fact that the pains frequently appear shortly after the amputation as well as the inability to relieve them by the various operations so far proposed including chordotomy precludes the plausibility of a neuroma. The author sees the cause of pain in the severance of the terminals of the pain conducting cutaneous nerves. The origin of the pain is to be found in the disturbance of the relationship between the pain conducting nerves on the one side and touch and temperature fibers on the other. Following an amputation there may exist two kinds of painful sensations those projected in the missing portion of the limb and those localized in the stump. The author found that severing the obturator nerve just below the obturator canal relieves the pain projected to the internal malleolus the inner aspect of the foot, the sole and the big toe, as well as the local pain affecting the mesial aspect of a stump of the thigh or the leg. For the pain projected to the external malleolus, the external aspect of the foot the little toe and the lateral aspect of the sole as well as for the pain localized to the outer aspect of the amputation scar the author recommends sectioning the nervus cutaneus femoris lateralis. Severance of the nervus cutaneus antibrachii lateralis is advised for phantom pains of the amputated thumb index and middle finger.

Thyroidectomy in Treatment of Heart Diseases—Bankoff reports the results of total and subtotal thyroidectomy in two groups of patients. In the first group of twenty belonged older patients with advanced heart disease angina pectoris and evidences of circulatory stasis. They were submitted to a total thyroidectomy. The basal metabolic rate in these patients was as a rule from 15 to 25 per cent above normal. Following the operation the basal metabolic rate fell to from 5 to 20 per cent below the normal the pulse became slower the blood pressure came down to normal and the attacks of angina pectoris did not return. In the second group were ten patients ranging in age from 19 to 30 who suffered from neurasthenia tachycardia and an increased basal metabolic rate without however any signs of thyrotoxicosis or organic heart disease. The patients of this group were submitted to subtotal thyroidectomy. There were no deaths in either group. The patients with decompensated hearts showed marked improvement. There was disappearance of dyspnea palpitations and edema. The patients of the second group were cured of their symptoms. The author recommends total thyroidectomy for cardiac patients in whom all medical therapy has failed to bring about an improvement. He recommends subtotal thyroidectomy for patients in whom medical treatment has failed to relieve tachycardia associated with neurasthenia and tremor.

Pseudospirochete in Blood in Disorder Resembling Recurrent Fever—Scholer relates the history of a man aged 64, whose disorder developed suddenly with severe headaches, fever, piercing pains in the epigastrium and in the umbilical region and vomiting. On the sixth day diarrhea set in but constipation followed hospitalization. Agglutination with three typhoid strains gave negative results. A swelling of the right leg developed, but the member was not sensitive to pressure and there were no signs of thrombosis. This swelling recurred. There were also recurrences of fever and of collapse-like conditions. The patient recovered in about two months. The case was diagnosed as severe general infection without primary lesion. Symptoms worthy of attention were irregular course of the temperature, a tendency to tachycardiac paroxysms, intercurrent pulmonary infiltration and pleurisy. The administration of arsphenamine was followed by rapid improvement. The first dose was followed by a strong reaction similar to that resulting from the administration of arsphenamine in recurrent fever. The author describes the isolation of the causal micro organism. Cultures were possible under aerobic and anaerobic conditions in well buffered, fluid mediums that contain protein or tissues. The organism is gram negative and readily stainable with the Giemsa stain. After the intraperitoneal introduction of the culture material in various species of animals, the organism appears in the blood or in the cerebrospinal fluid after various lengths of time. The author cites reports from the literature in which unusual types of spirochetes were discovered and emphasizes the necessity of making cultures in fluid mediums and of observing those cultures for a long time. He also stresses the favorable therapeutic action of neoarsphenamine in cases of general infection.

Antagonistic Action of Simple Herpes in Infectious Diseases—Naegeli made observations which convinced him that the activated herpes virus plays an important part in the action of fever therapy of dementia paralytica. He observed rapid therapeutic effects when in the course of fever therapy a noticeable attack of herpes appeared. In a small number of patients in whom herpes did not appear during malariotherapy and in whom the effects of the therapy were negative, the transmission of herpes and the subsequent activation with fever therapy resulted in an improvement of the clinical picture. Statistics indicate that infections of the cerebrospinal fluid are less frequent in patients with herpes than in patients without herpes. Moreover, in countries in which syphilis is frequent but in which malaria is endemic and herpes rather frequent, late syphilis is almost absent in spite of the inadequate treatment of early syphilis. Tabes and dementia paralytica are more frequent in men than in women whereas in women there is a greater incidence of herpetic manifestations. Herpes although comparatively harmless for human subjects, may cause fatal encephalitis in rabbits. Thus it is possible that the herpes virus is capable of destroying spirochetes. The author thinks that the remissions and cures of dementia paralytica are not the result of the malaria because its action is regional, as only the spirochetes in the brain are killed and not those in the skin and in the internal organs. Although the cerebrospinal fluid may become seronegative malariotherapy does not change a positive blood Wassermann reaction into a negative one. Moreover, results similar to those obtained with malariotherapy can be produced with recurrent fever, with rat bite fever and even with coli-vaccine. In this connection he points out that the endovenous administration of coli-vaccine results in attacks of herpes more often than the administration of any other vaccine. The author believes that infection and fever production are only indirect therapeutic factors, in that they activate the herpes virus which exists in the latent stage in many human beings.

 *Large Respiratory Minute Volume with Especial Consideration of Cause of Poisoning with Acetyl-salicylic Acid A. Sylla—p. 314
 Evacuation and Irrigation in Pleural Exudates in Artificial Pneumothorax E. Kornitzer—p. 318

Large Respiratory Minute Volume—Sylla states that an enlarged respiratory minute volume is frequently observed during rest. In many cases with slight increases, the cause is to be found in hyperventilation developing as the result of psychic or motor unrest. This hyperventilation leads to an increase of the carbon dioxide elimination by the respiratory air and of the respiratory quotient above 1. If hyperventilation persists for a longer period, blood alkalosis (respiria) results. Slight increases of the respiratory exchange in hyperventilation, characterized by a large respiratory minute volume and by an increased respiratory equivalent (above 35) are caused by the enlargement of the respiratory quotient and by the greater effort caused by the hyperventilation. In the determination of the basal metabolism it is therefore advisable to calculate also the respiratory minute volume and the respiratory quotient the more so since the additional effort is slight. Unusually large respiratory minute volumes with great respiratory quotients are observed in severe acidoses of the blood (uremia and hepatic and diabetic comas). In cases of poisoning deviations are observed. The author demonstrates in several cases that as the result of a central irritation, a large respiratory minute volume may develop without an increased respiratory quotient and that on the other hand, in spite of a severe acidosis of the blood there may be no hyperventilation probably because the irritability of the respiratory center has been reduced. The respiratory minute volume is generally considerably larger when air is inhaled than when pure oxygen is inhaled. The respiratory quotient shows the corresponding behavior. The opposite behavior is observed in lesions of the respiratory center.

 Poisoning During Childhood H. Tunger—p. 268
 Evaluation of Diphteria Antitoxin in Serum and Vaccination Experiments with Concentrated and Purified Form of Formal Toxoid H. Holzapfel—p. 280

Pathogenesis of Erythema Nodosum—Goldberg-Curtis shows that true idiopathic erythema nodosum is a cutaneous reaction to an infection the pathogenic organism of which is as yet unknown. Symptomatic erythema nodosum may develop in the course of nearly every infectious disease and is a cutaneous reaction to toxic substances. During childhood the majority of cases of erythema nodosum are closely related to a tuberculous process quite frequently to a primary tuberculous process. Erythema nodosum in tuberculous children does not necessarily imply an unfavorable prognosis. Tubercle bacilli are frequently demonstrable in the fluid obtained from gastric irrigation of these children. The detection of bacilli in the blood or the cultivation of bacilli from erythema nodules are not definite proof of the tuberculous nature of the skin disorder. Quite often it is possible to detect a source of infection in the environment of the patient, and occasionally several cases are seen in one family. Clinical and roentgenologic signs of pulmonary tuberculosis are quite frequent in the course of erythema nodosum, but signs of extrathoracic tuberculosis are rather rare. During the stage of prodromal fever there is frequently a change in the formerly negative tuberculin reaction. Prophylactic vaccination with BCG apparently can prevent the appearance of erythema nodosum as well as of a positive tuberculin reaction, in spite of a strong source of infection. The author thinks that all forms of erythema nodosum are indications of a change in the allergic condition of the organism. She rejects the true tuberculous nature of the disorder but admits that cases which present the clinical aspects of erythema nodosum and the pathologic histologic aspects of the tuberculi although rare do occur. The assumption that erythema nodosum is caused by a tuberculous filtrable ultravirus has not been proved as yet. It appears that the polymorph erythemas are closely related to

erythema nodosum, for here too the eruption of erythema is accompanied by fluctuations of the allergy in tuberculous patients. The high incidence of erythema nodosum in the nordic countries permits the assumption of a racial predisposition (in blood persons). Moreover, this predisposition may explain also the greater incidence during childhood.

Chronic Intestinal Disturbances and Amebic Infections—Fischer gives the history of a man who, during the war contracted malaria and paratyphoid. The intestinal disturbances never ceased completely. The disorder was never completely clarified until the patient was subjected to a thorough examination in an institute for tropical diseases. Amebas were discovered in the stool. The dysenteric symptoms yielded quickly to treatment. The author emphasizes that, if patients who at one time have been in the tropics have chronic complaints, it is absolutely necessary that they be subjected to a thorough examination by a physician who is familiar with tropical diseases.

 *Ovarian Cycle and Carbohydrate Metabolism Galactose Tolerance J. Bloch and A. Bergel—p. 267
 Thyroid and Circulation F. Kisch—p. 297

Glycemic Reaction During Menstrual Cycle—Bloch and Bergel show that during the premenstrual and the menstrual period of women with a normal cycle the glycemic reaction, following a dextrose tolerance test, is different from that observed during the interval. This difference in the glycemic reaction is neither the result of menstrual impairment of the hepatic parenchyma nor caused by abnormal resorptive conditions in the gastro-intestinal tract but is the manifestation of an increased irritability of the autonomic nervous system. The menstrual changes in the glycemic reaction consist in an increased hyperglycemia, an earlier maximal increase, a noticeable hypoglycemic phase and occasionally the formation of a second peak. These abnormalities of the menstrual glycemic reaction are found especially in women with sympathetic disharmony, in whom menstruation is frequently accompanied by alimentary glycosuria.

Ossification of Iliolumbar Ligament—Miller agrees with Lowman and Steindler, who consider anomalies in the taxing or in the static mechanical factors the most important causes of the calcification or ossification of the iliolumbar ligament. Moreover, it seems that inflammatory processes are an etiologic factor, but it cannot be definitely determined whether in this case the ossification is likewise a static one that effects immobilization of the joint or relieves the joint. To what extent anomalies of formation are involved cannot be estimated as yet, but this possibility cannot be entirely disregarded. This theory, which considers the ossification primarily a reparative process, makes an operative intervention on the ligament seem undesirable in the majority of cases.

Ovarian Cycle and Galactose Tolerance—Bloch and Bergel describe their studies on galactose assimilation during the ovarian cycle. They found that it was increased during the premenstrual and the menstrual periods. They show that this increase is not caused by a direct hepatotropic action of the ovarian hormone but is rather the manifestation of a condition of the neurosympathetic and hormone systems that prevails during these phases of the ovarian cycle.

Radical Treatment of Varicose Veins L Moszkowicz—p 274
*Treatment of Traumatic Wounds and Their Sequels H Kunz—p 274

Schick Test and Susceptibility to Diphtheria—Leach and Pösch point out that Schick and Michiels maintained that a negative Schick test indicates an antitoxin titer of not less than 0.03 antitoxin unit for each cubic centimeter of serum. Later the lower limit of protective action, the so-called Schick threshold, was placed at 0.02 and then at 0.01 antitoxin unit for each cubic centimeter of serum. However, it was found that a negative Schick test does not exclude the possibility of contracting diphtheria. In studies on 4,800 children the authors found that seven children with a negative Schick test developed diphtheria. They further report studies on 215 children. Not only were these children subjected to Schick tests but their blood was carefully examined for its antitoxin content. It was found that in 13.6 per cent of those with a negative Schick test the antitoxin content of the blood was below the minimum required for protection. The authors conclude that the negative Schick test is not entirely reliable as regards the susceptibility for diphtheria as well as the antitoxin content but they think that a positive Schick test indicates definitely a susceptibility for diphtheria.

Treatment of Traumatic Wounds—After discussing wound excision according to Friedrich, Kunz evaluates the seroprophylaxis of tetanus and says that it is not necessary in every open wound. He maintains that the danger of tetanus is slight in industrial injuries, particularly in those occurring in the metal industry. In severe street accidents, however, seroprophylaxis is necessary, and it is advisable to protect the patient also against gas gangrene, although the prophylaxis of the latter does not always preclude its development. With regard to wound infection, the author says that the old surgical methods (incision and drainage) are still the most widely used. However, in some clinics the incision with the electric knife is now employed only for certain types of wounds. Open wound treatment in combination with continuous irrigation or with the water bed is found effective particularly in sanious wounds of the region of the pelvis. The cod liver oil bandage according to Löhr is used with good success in the treatment of large infected wound cavities and of tissue defects. In the treatment of pyogenic general infections, early and repeated blood transfusions are the most effective method. The author emphasizes that the opinion of the uselessness of serotherapy of manifest tetanus is incorrect and he advises intensive treatment. Intravenous, intramuscular and intraspinal injections of serum should be given several days in succession. Serotherapy is likewise advisable in gas gangrene.

*Modification of Antibody Concentration by Specific Desensitization in Pollen Allergy G Albus—p 703
*Spleen and Water Exchange R Tislowitz—p 704

Influence of Small Doses of Parathyroid Extract on Magnesium—Coppo and Pisa described studies on the magnesium in rats treated with small doses of parathyroid extract which produce a noticeable reduction in the magnesium content of the organism. An analysis of the values in the different rats disclosed that the only animal in which the ash residue revealed no increase in calcium lacked also a reduction in the magnesium content. Moreover the magnesium content showed the greatest decrease in cases in which the calcium values showed the greatest increase. A survey of all these observations discloses that even small amounts of parathyroid extract

produce changes in the mineral constituents: an increase in the calcium and a reduction in the magnesium content. The authors conclude that their analyses furnish an important contribution to the theory that assumes a direct relation between the function of the parathyroids and the biochemistry of magnesium.

Desensitization in Pollen Allergy—Albus points out that the specific desensitization of hay fever patients by means of pollen extract has proved of practical value, but that the objective proof of its action is still lacking. It was his aim to furnish this proof. He mentions two theories that have been advanced to explain the mode of action of desensitization and then describes studies proving clearly that the treatment with pollen extracts exerts a noticeable influence on the reactions of the sensitized organism, in that it neutralizes the antibodies lodged in the cells and thus effects a reduction in the antibody values. He thinks that his studies prove the second of the two theories, according to which the antigen (pollen extract) reaches the cellular antibodies in subthreshold value and neutralizes them so to speak, which becomes manifest in a reduction of the antibodies. If now allergen enters again, it finds no reactive counterpart, there is no antigen-antibody reaction and allergic manifestations do not develop. Thus the practicability of the active desensitization has been proved objectively.

The Spleen and Water Exchange—Tislowitz describes studies demonstrating that spleen extracts increase the water storage of the tissues, reduce the circulating quantity of water and inhibit diuresis. He maintains that the spleen is important in the mechanism of the water exchange not only as a depot organ but also because it is a part of the reticulo-endothelial system. He says that further investigations will have to prove whether the reticulo-endothelial system has a mechanical storage action or whether the reaction of the vessels (similar to the blockage of the hepatic veins) plays a more important part.

Artificial Formation of Sphincter in Urinary Incontinence in Women (Plastic Operation on Pyramidal Fascia of Bladder) N P Werhatsky—p 489
Transvesical Diaphanoscopy H Hellendall—p 505

Operation for Juxtavesical Ureteral Calculi—Kneise points out that juxtavesical ureteral calculi can be removed by lumbo-abdominal, extraperitoneal ureterolithotomy and by the vaginal route. He thinks that the vaginal method is inadvisable in the majority of cases and that in cases in which the extraperitoneal operation involves too many difficulties (particularly in stout women) only the transperitoneal method remains. The latter method has certain disadvantages. One is the danger of peritoneal infection in case an infection exists; however, the author does not consider this danger grave. Another shortcoming is that in cases in which the juxtavesical calculus is from 4 to 5 cm away from the bladder the uterine adnexa of the involved side are in the way, and some surgeons resort to their extirpation. The author considers this unjustified and describes a method by which he removed a ureteral calculus that was wedged in 4 cm away from the ureteral ostium. He opens the abdomen in the median line or by a suprasymphysial transverse incision. Then he grasps with a strong clamp the round ligament of the side on which the calculus is located and draws the uterus upward and outward. Thus the anterior portion of Douglas' pouch is exposed and occasionally the stone can be felt. Then the vesical peritoneum is opened and the bladder is pushed downward. The peritoneum is pushed aside from the ureter and gradually the stone is reached. The site at which the uterine vessels cross the ureter comes into the operative field. They are not doubly severed but are pushed upward, so that they disappear under the round ligament and the peritoneum. Thus the only vessel that remains in the operative field is the superior vesical artery. If the calculus is large and can be felt it is unnecessary to remove much of the ureter from its surrounding connective tissue. Before the ureter is opened the pelvis is slightly more elevated, and careful tamponade is done. Then the ureter is incised, the calculus removed, the patency of the ureter verified and the wound sutured. The author says that the operation presents no difficulties for any

one familiar with Wertheim's operation. He emphasizes that the operation is intended only for the juxtavesical concretions that are not more than 4 or 5 cm removed from the vesical ostium.

- *Parenteral Administration of Extract of Convallaria Root B. F. Votchal and Ts. Ya. Kogan—p. 114

Velocity of Circulation—Berinskaya and Meerzon studied the velocity of circulation in 162 patients utilizing Leschke's method which consists of a rapid injection in the cubital vein of from 0.6 to 1 cc of a 50 per cent solution of calcium chloride. This is followed in a few seconds by a sensation of heat felt, as a rule first in the tongue and next in the throat, perineum, chest, abdomen, hands and feet. In a group of healthy persons and in patients presenting no involvement of the cardiovascular system the velocity of circulation varied from ten to fifteen seconds the average being 11.5. In a group having compensated cardiovascular lesions the velocity of circulation was from ten to seventeen seconds the average being 12.2. In a group of patients with signs of decompensation the velocity of circulation varied from thirteen to forty-four seconds giving an average of 20.1. The authors conclude that circulatory insufficiency results in slowing of the velocity of circulation and that the greater the decompensation the more pronounced the slowing. Marked slowing of velocity has a bad prognostic significance. Acceleration of the velocity following any therapeutic procedure denotes its effectiveness and suggests a favorable prognosis. The authors point out the following disadvantages of Leschke's method: irritation of the endothelial lining of the vessel by the highly concentrated calcium chloride solution; necessity for rapid injection into the vein which may lead to paravenous spilling and necrosis and possibility of thrombosis.

Parenteral Administration of Extract of Convallaria Root—Votchal and Kogan report their results with parenteral administration of a new fluid extract of the root of *Convallaria majalis* in twenty-six patients having decompensated hearts. They state that, although it is almost without any effect when given by mouth, it possesses all the effects of the digitalis group when administered parenterally. Its more rapid effect, shorter duration than that of digitalis, pronounced negative chronotropic effect and insignificant cumulation bring it closer to strophanthin. The same care in dosage must be exercised when giving it as with strophanthin because of rapidly developing signs of intoxication in case of an overdose. While evanescent, the symptoms are those of involvement of the path of conduction of the heart beat and may lead to ventricular fibrillation. The authors recommend hypodermic administration. The maximal dose is 40 frog units. They state that in some of their cases its diuretic effect was greater than that of digitalis or strophanthin. In addition, it has a soothing effect approaching that of a hypnotic state. Because of these properties, it is suggested as a substitute for strophanthin.

- Digital Fracture K. A. Rombach—p. 1112

Dissociated Skin Reaction—Boer and Van Delfse report the clinical and bacteriologic observations on a child aged 8, presenting a dissociated skin reaction. The patient was completely insensitive to human and bovine tuberculin, even in strong concentrations (1:100) injected intradermally. When an intradermal injection of 0.1 cc of a culture filtrate of tubercle bacilli sterilized by heat was administered the patient showed

a marked positive reaction. The citrated blood of the patient cultivated on a Besredka medium gave three times a culture of acid and alcohol resisting strains which were not transferable by inoculation or pathogenic to guinea pigs. Injections of the patient's sputum in guinea-pigs did not occasion tuberculosis in the animals, when, however, the same guinea pigs were later given two injections weekly of an acetone extract of tubercle bacilli, permanent tuberculous lesions appeared. The authors isolated from these lesions several tubercle bacilli cultures with special characteristics similar to those described by Valtis and Van Delfse (*Compt. rend. Soc. de biol.* 113 847, 1933) and found by these authors in guinea pigs infected with filtrates and treated with acetone extract.

Two Unusual Complications in Delivery—In a secundipara in whom deep episiotomy was done at the first delivery, the head pressed strongly against the perineum and during a powerful bearing down pain was expelled through the perineum, the body following easily. In a primipara the rectovaginal septum was ruptured during a strong bearing down pain after the buttock had shown itself at the vulva, and the entire right leg of the child appeared through the anal opening. Delivery was spontaneous. The anal sphincter was intact. The place of rupture in the perineum was passable for three fingers. Meyer ascribes the rupture to the unfavorable position of the right leg of the fetus which in the breech presentation had exerted an unequal pressure on the rectovaginal septum during the bearing down pains.

- *Concentration Index of Urea and Its Significance in Surgery E. W. Gøthgen—p. 181

Fulminant Tonsillopulmonary Toxemia in Infancy—Heerup treats of a violent, acute, sporadic or nosocomial infection usually fatal within twenty-four hours, in children less than 18 months of age who have in most cases had several catarrhal infections. Clinically, he says, a septic, hyperpyretic picture without demonstrable focal disorders is seen. Patho-anatomically there is a mild tonsillopharyngitis and a hyperemic edematous change in the lungs. On bacteriologic necropsy (systematic bacteriologic excision of specimens in sterile necropsy with the organs in situ), tonsils and lungs show massive growth of staphylococci, streptococci and pneumococci. In theoretical explanation the author considers the possibility of increased virulence of the microbes resulting from infection transmitted from child to child or (and?) an allergic pulmonary edema due to sensitization with diffuse spread of microbes in the lung tissue, and a violent resorption of toxin from the tonsils and lungs.

Concentration Index of Urea and Its Significance in Surgery—Gøthgen considers this index a better indication of the immediate condition after operation than that afforded by determination of the blood urea alone. Proper evaluation of the results calls for repeated examinations. The urea concentration index is the relation of the grams per hundred cubic centimeters of urea in the urine to the grams per hundred cubic centimeters of urea in the blood. In bed patients with normal kidneys the index is about 50. With small diuresis and marked urea formation it may rise to more than 100. Values below 30 are seen only when the diuresis is extremely high. The author finds that after operation there are in patients with previously normal kidneys (1) normal urea in the blood and index of more than 100 in the first period or (2) slightly increased urea in the blood and index between from 50 to 100 indicating a complication, or index of less than 30, pointing to a more serious complication and grave prognosis if the index continues low, or (3) marked increase in the urea in the blood with low index often below 10, showing a grave, often irreparable complication and extremely grave prognosis.

PAINLESS JAUNDICE

REUBEN OTTENBERG, M.D.

NEW YORK

The adequate presentation of the subject of jaundice would require a book rather than a short article. I will therefore not attempt, even in outline, to cover the whole subject. Rather as a practical clinician addressing fellow clinicians I will limit myself to one type of jaundice. It is the type in which prompt diagnosis and correct treatment are of the greatest importance. It is also the group in which mistakes are most commonly made. I refer to the jaundice of adults coming on without pain or with relatively little pain. This includes about one third of all cases of jaundice.

Why is painless jaundice in adults particularly important? Because it is vital that as soon as possible the essential decision should be made whether the patient is suffering from a surgical or a medical disease. The decision as to which particular variety of surgical or medical jaundice is of little importance compared to the decision as to whether the case is surgical or medical.

CLASSIFICATION

In practice the newer classification of jaundice introduced by Rich based on recent researches on the mechanism of jaundice is of less value than the older and simpler classification of McNee,¹ because the latter corresponds to the decision that the clinician is called on to make. McNee divides all jaundice into (1) hemolytic, (2) toxic infectious and (3) obstructive. For the present purposes medical jaundice includes the first two groups, hemolytic and toxic infectious. Obstructive is practically synonymous with surgical jaundice, whether the obstruction is due to stone, carcinoma, stricture or external pressure by a variety of other causes. (This does not imply that all cases of obstruction are cases for immediate operation.)

In the present discussion the subject of hemolytic jaundice will be omitted altogether for the reason that the condition presents so many peculiar features that, when adequate study has been made, the diagnosis is usually easy. It seldom enters into the question of differential diagnosis.

DIAGNOSIS

In the great majority (from 70 to 80 per cent) of cases of jaundice, diagnosis is made without difficulty at the bedside on the basis of the clinical history. The

difficulty is in the other 20 to 30 per cent of the cases and is due to the well known tendency of all clinical pictures to vary within wide limits. The pain of hepatic degeneration, usually mild or absent, may be severe. Conversely, partial or complete obstruction of the common duct by stone ordinarily very painful, occasionally is painless. While it is true that most jaundice in older persons is obstructive, nevertheless acute degeneration can occur at any age, occasional cases of stone in very young persons are encountered. In this as in most other fields of medicine the word "never" can be used only in the Gilbertian sense. "What never?—Well hardly ever." It is in this sense that the word "painless" in my title should be interpreted.

Unfortunately there is at present no clinical or laboratory method of distinguishing partial or complete obstruction of the bile duct from partial or complete suppression of bile. In each case one has to weigh numerous pieces of evidence in favor of the one or the other diagnosis. A very precise and full history is perhaps more important than anything else. It must be remembered in considering carcinoma involving the bile ducts that gallstones are found in almost a third of the cases, so that a previous history suggestive of cholelithiasis or cholecystitis does not weigh against the diagnosis of new growth. The history of the appearance of the stools is very important. In hepatic jaundice they are white or clay colored for only a short time or for irregular periods. Persistence of such feces over a long period of time points to obstruction by a new growth. The recent occurrence of arthritis or urticaria is somewhat in favor of toxic hepatitis. All the various toxic substances that can be taken or administered must be kept in mind and must be inquired for. Most important of these are arsphenamine, cinchophen, poison mushrooms, carbon tetrachloride (carbena and the like), chloroform, tribrom-ethanol phenylhydrazine, trinitrotoluene, phosphorus. As some of these, and a great many of the rarer chemicals that can cause hepatic degeneration are used in industry, the question of the patient's occupation is important.

Compared with the history, the physical examination of the patient usually contributes relatively little to the diagnosis. The most important positive finding, perhaps, when it occurs, is the well known Courvoisier gallbladder. It is felt almost exclusively in obstruction due to carcinoma of the head of the pancreas or common bile duct. However it is by no means found in all such cases. In fact, it is found in only a little more than half of them. And on rare occasions a similar easily palpable gallbladder may be found in obstruction due to stone. I have seen one such case myself. Nevertheless the Courvoisier gallbladder should always be searched for and evaluated in diagnosis. It has been suggested that when it is searched for and not found

¹ Rolleston H. D. and McNee J. W. *Diseases of the Liver, Gall bladder and Bile Ducts*, ed. 3. London: Macmillan Company, 1929, p. 568.

² The present discussion is based on an analysis of 100 consecutive cases of jaundice personally observed in the past year. No attempt is made at statistical treatment as this would require a larger series.

large doses of some sedative should be given to produce complete abdominal relaxation. I am not entirely sure of the wisdom of this plan, because in a case that might turn out to be one of toxic degeneration of the liver a large dose of any drug should be given only with great caution. One of the difficulties with the Courvoisier gallbladder is that a tongue-like extension of one of the lobes of the liver sometimes feels so much like the gallbladder as to deceive all observers.

The palpatory features of the liver, whether large or small, firm or soft, smooth or irregular, usually help little in making the differential diagnosis. Distinctly palpable nodules, of course, often point to metastatic carcinoma, which, by involving bile ducts, may become the cause of obstructive jaundice. A palpable mass either in the abdomen or in the pelvis must invariably be sought in an effort to rule out primary new growth of the gastro-intestinal tract. A palpable spleen is very suggestive of hepatic degeneration.

Other features of the examination such as the intensity of the jaundice and its character, whether yellow, green or blackish, are of no practical value. The occurrence of itching likewise does not in the least help to differentiate between obstructive and hepatic jaundice.

PHYSIOLOGY OF THE LIVER

In recent years, interest in the fundamental physiology of the liver has been intense. New clinical and laboratory tests have been learned which are collectively of great value in making the special differential diagnosis that interests the physician. However, it must be said at the start that every one of the tests so far introduced occasionally fails the clinician in a critical situation. Also, many of the procedures useful in the study of liver and biliary tract disease without jaundice cannot be applied in the presence of jaundice. Among these last may be included x-ray visualization of the gallbladder and liver function tests by the dye injection methods and by the bilirubin loading method. I shall mention only those of the newer tests which I have found to be of practical value.

The most ancient and simple and, all in all, one of the most important examinations is that of the patient's stools, to determine whether or not any bile is entering the intestinal tract. What is really tested for, of course, is not bile pigment as such but urobilin, the brown pigment of the stool produced by the action of intestinal bacteria on bilirubin. There are several extremely simple clinical tests for this pigment. The mercuric chloride test does not require extraction but takes time, the test for fluorescence after the addition of zinc salts can be done in a few minutes on an alcohol extract of a small fragment of feces. When the stool is gray or distinctly white, the urobilin test is nearly always negative. When it is brown or at least yellowish, the urobilin test is nearly always positive. The examination of the stool should form part of the physical examination of the patient at the first and all subsequent visits. If the patient has not saved a specimen of the stool for the doctor to examine it is nearly always possible to obtain a few particles for inspection by inserting the finger into the rectum.

The second way of answering the same question of whether any bile is entering the intestine is by means of duodenal drainage. This, when successful, has the advantage that the test is somewhat more direct than the examination of the stool. Mere traces of bile pigment are easily recognized by their color in the duodenal contents. When the result is negative, unless fluor-

oscopy has been done on the patient with the duodenal tube in place, one is never sure that the tube actually reached the duodenum. However, drainage that was previously strongly acid and then becomes distinctly alkaline is usually sufficient evidence on this point. The one advantage of the stool examination as compared with the examination of the duodenal contents is that it can easily be repeated every day, while such frequent repetition of duodenal drainage is not only exhausting to the patient but in cases of liver degeneration actually dangerous on account of the temporary starvation involved.

A third way of checking up on the question of whether any bile is entering the intestinal canal is by daily examination of the urine for urobilinogen or urobilin. Complete absence of these substances indicates total acholia of the stools.

The frequent, if possible daily, determination of the question whether any bile or none is entering the gastro-intestinal tract is of particular importance. The mere single determination of the total absence of bile is of little significance. It is only the persistent and total absence of bile over a period of six or seven days or more that is significant. This occurrence is the rule in cases of malignant obstruction of the bile duct, there is an occasional exception, due to secondary ulceration. Persistent acholia rarely occurs in other forms of jaundice. In obstruction by stone and in suppression due to hepatic degeneration, transient absence of bile occurs. But obstruction due to stone is only rarely complete. Usually a little bile does enter the intestine, and the detection of this little is the chief advantage of duodenal drainage. Total absence of bile is common enough in hepatic degeneration and may occur even in instances, such as those of catarrhal jaundice, which run a mild course. However, it is nearly always transient, seldom lasting more than from one to three days (except perhaps in the terminal stages of acute yellow atrophy of the liver).

Other features of the examination of the duodenal contents, such as the finding of numerous cholesterol crystals, calcium bilirubinate precipitate, pus cells or bacteria, may occasionally count in the balance in favor of cholelithiasis or of cholangitis but are of relatively difficult interpretation and must be evaluated with considerable caution.

The next clinical test is one which, like the foregoing, should be repeated, if not daily, at least very frequently. It is the determination of the amount of bilirubin in the blood serum or plasma. I say advisedly the amount of bilirubin because the mere determination of the character of the bilirubin, that is, whether the van den Bergh reaction is direct or indirect, is (since consideration of hemolytic jaundice is purposely being excluded) of no value in differentiation, both obstructive jaundice and hepatic jaundice produce the direct van den Bergh reaction.

I will deviate for a few moments from the strictly practical plan of the present paper in order to point out the real value and importance of the determination of whether blood serum gives the direct van den Bergh reaction or only the indirect. There seems to be current the idea that this determination is of very great diagnostic value. It is not—or is only rarely so. But the study of this reaction has come to be of enormous significance in understanding the mechanism of jaundice in different diseases. For it has been quite well established that that bilirubin which gives the indirect reaction only is bilirubin which has been produced by

the reticulo-endothelial system, mostly outside of the liver it is circulating in the blood merely because it has not yet been excreted by the liver cells, whether because the bilirubin was produced in excess as in hemolysis, or because the liver for some reason is functioning poorly. It is "retained" bilirubin. That bilirubin which gives the direct van den Bergh reaction is bilirubin which has already been secreted by the liver cells into the bile canaliculi but found its way back into the blood stream because of back pressure (obstruction) or of actual necrosis of liver cells. It has been "regurgitated" and like the bilirubin in bile itself gives the direct reaction.

A glance at the list of causes of "retention jaundice," and that of causes of "regurgitation" jaundice in Rich's³ classification will show that there is seldom any difficulty in differentiating the diseases in the one group from those in the other. On the other hand, all the forms of jaundice that are hard to differentiate from one another are in the second group—regurgitation

diazo color with Ehrlich's diazo reagent under specified conditions, and then diluting it until it matches a color scale representing a known amount of bilirubin. The result is expressed either as a dilution (1:200,000 being average normal) or, better, as milligrams per hundred cubic centimeters (0.5 mg per hundred cubic centimeters representing the average normal). The quantitative van den Bergh method is almost specific for bilirubin. It has the disadvantage that it is a precipitation method and that an unknown and highly variable amount of bilirubin is always lost in the precipitation.

The determination of the icterus index of Meulengracht⁴ is really nothing but finding out how many times it is necessary to dilute the given sample of serum until its color matches that of a standard 1:10,000 potassium bichromate solution. The standard is permanent, and for approximately correct results an elaborate colorimeter is not essential. The determi-

Rich's Classification of Jaundice

(Condensed)

jaundice. And as these all give the direct van den Bergh reaction in the serum, as well as bilirubin and bile salts in the urine, these tests are of little differential value in diagnosis.

BILIRUBIN

The blood examination is of far greater value than inspection of the skin—it readily lends itself to quantitative estimation, and the response of the skin to changes in the blood is only very slow. Skin jaundice usually only sets in twenty-four hours after the onset of bilirubinemia, and in the subsidence of jaundice the blood loses its excess of bilirubin more rapidly than the pigment disappears from the skin. Daily clinical inspection of the color of the urine is of some, though not of quantitative, value in watching changes in the degree of jaundice.

In determining the amount of bilirubin in the blood, two different methods are employed. The first, the quantitative van den Bergh test, is done by precipitating the serum proteins with alcohol then developing the

nation is an easy, almost bedside, one that can be carried out with very little trouble by the clinician himself. It is true that bilirubin is not the only yellow colored substance in the blood serum. However, the only other yellow colored substance that enters into consideration, namely carotene, is present in such small amounts as to cause confusion with extraordinary rarity. It practically needs no consideration. In a number of years I have only once seen a case, one of diabetes, in which the amount of carotene in the serum was enough even to raise the question of jaundice.

For the determination of the level of blood bilirubin and even more important of the variation of this level from day to day and from week to week, the icterus index is more accurate than the van den Bergh test. For this reason and on account of its simplicity it is to be preferred. The important practical point for the technic of the icterus index is that the blood serum or plasma must be collected without hemolysis. The normal figure for the icterus index is 5.

³ Rich A R Bull Johns Hopkins Hosp 47: 338 (Dec) 1930

4 Menlengracht E Deut ches Arch f klin Med 132 285
(July) 1920

The van den Bergh test as a quantitative method is preferred by some to the icterus index, and the two methods do not always correspond. Thus, since 0.5 mg of bilirubin by the van den Bergh method usually corresponds to an icterus index of 5, 1.5 mg should correspond to an icterus index of 15. (This, parenthetically, is the concentration at which clinical jaundice usually begins to appear.) Three milligrams by the van den Bergh method should correspond to an icterus index of 30, 30 mg to an icterus index of 300, and so on. These exactly parallel figures however are not generally found. Elton⁵ has shown the discrepancy to be due not only to the loss of bilirubin in the precipitation of the van den Bergh method but also partly to the fact that bilirubin, which gives the indirect reaction, gives less of the yellow color than direct reacting bilirubin.

Experience with more than a hundred cases has convinced me that in following the course of mild or slight jaundice and especially in detecting so-called

growth is more likely to be between 150 and 250. What characterizes the bilirubinemia of cancerous obstruction is its relative constancy from day to day. It gradually reaches a fairly high level and then stays at about the same level. The high figures from hepatitis tend to be reached more quickly and then either to commence to show recession or fluctuation or to progress to a rapidly fatal issue. In the range of what may be called moderate grades of jaundice, indexes of from 20 to 200 (2 to 20 mg), neither the height of the jaundice nor the character of the curve is of any really differential value.

CHOLESTEROL AND CHOLESTEROL ESTERS

Of equal importance with the determination of blood bilirubin perhaps indeed of greater differential value is the determination of the cholesterol of the blood plasma. It is remarkable that the most fundamental clinical facts concerning it known today were discovered in 1862 by Austin Flint⁶. Seventy-two years ago Flint demonstrated that cholesterol is removed from the blood and excreted by the liver in the bile. He showed by chemical analyses of blood that in jaundice due to obstruction of the bile ducts the percentage of cholesterol in the blood increases, while in other forms of jaundice and particularly in acute catarrhal jaundice, this does not occur. In his enthusiasm over his new observations Austin Flint exclaimed "What the discovery of urea has done for diseases which come under the head of uremia the discovery of the function of cholesterol may do for the obscure diseases which may hereafter be classified under the head of cholesteremia." The reason that these important facts were not used by clinicians until recently was that methods such as those now available for the determination of blood cholesterol on small amounts of blood had not yet been developed.

The normal blood cholesterol is about 200 mg per hundred cubic centimeters of blood. With complete obstruction of the bile ducts the level increases greatly, to from 300 to 400 mg or more, and usually remains high until late in the disease, when nutrition fails badly. In partial or intermittent obstruction, as in cases of calculus the increase in blood cholesterol is usually moderate in degree, from 250 to 300 mg. In the various forms of liver degeneration there is usually no increase or only a moderate increase in the very early stage and again in convalescence. In severe liver degenerations there is frequently marked decrease, and this has considerable prognostic importance. I shall refrain in the present clinical discussion from an explanation of these facts because recent physiologic discovery, especially the work of Sperry who showed that about two thirds of the cholesterol of the stool is excreted by the intestine has completely upset the simple conceptions which prevailed until a few years ago. The clinical facts, however, are well established and distinctly useful.

There are a few other causes of increased blood cholesterol besides obstructive jaundice. Of these, the important ones to remember are uncontrolled diabetes and nephrosis.

Aside from the behavior of the total cholesterol of the blood, a new diagnostic criterion of considerable value has been introduced in recent years in the determination of the cholesterol esters of the blood plasma. Since cholesterol is an alcohol, it enters into combination with the higher fatty acids such as palmitic stearic and

Chart 1—The difference in behavior of blood cholesterol and cholesterol esters and of urine and fecal urobilin in toxic and obstructive types of jaundice

latent jaundice, the quantitative van den Bergh method is inaccurate and misleading as compared with the icterus index. If clinicians will look at the blood serum themselves instead of merely accepting a laboratory report, they will easily convince themselves of this.

With regard to the level of blood bilirubin, there are two points to observe, the height to which accumulation of bilirubin in the blood goes and the persistence with which it stays there. Unfortunately, the evidence on neither point is conclusive in separating obstructive from intrahepatic jaundice. Nevertheless when added to other evidence it is of some value. While extremely high icterus index figures 200 or 300 or over can occur both in acute degeneration of the liver and in complete bile duct obstruction by a malignant condition, the highest figures, indexes over 300, usually occur in cases of liver degeneration. An obstruction from a malignant

⁶ Flint, Austin. A new Excretory Function of the Liver, J Am M Sc October 1862

oleic acids to form cholesterol esters. This mechanism probably plays an important role in the absorption of fats from the intestine and in the transportation of fat in the blood. The liver is capable of forming esters by combining cholesterol and fatty acids. The liver also contains an esterase capable of breaking up this combination of fatty acids and cholesterol, this is believed to be responsible for the fact that only cholesterol as such and not cholesterol ester is excreted in the bile. Normally from two thirds to three fourths of the cholesterol of the plasma is in the form of cholesterol esters.

In obstruction of the bile ducts, along with the increase in the total blood cholesterol, there is a parallel although not quite so great an increase in the percentage of cholesterol esters in the blood. In all forms of hepatic degeneration the tendency is for the proportion of cholesterol esters to fall. In mild cases this drop in proportion of cholesterol esters may be only to around 40 per cent. In severe cases the esters often completely disappear or are within the lowest range, under 20 per cent, in which accurate determination by clinical methods now available cannot be made. As the determination of cholesterol esters is rather a delicate one, in which error is easily made, a diagnosis should not be based on a single determination but the analysis should always be repeated and all analyses should be done in duplicate. In the presence of jaundice the persistent absence of cholesterol esters from the blood is grave prognostic evidence, pointing toward serious damage of the liver parenchyma. It is of special value in enabling one to make the correct prognosis early in those occasional cases which commence mildly like simple catarrhal jaundice but which go on ultimately to death from acute yellow atrophy of the liver. Before the introduction of the cholesterol ester determination there was no way of detecting these cases and the physician was usually surprised by the sudden onset of cholemia in what had appeared to be a harmless disease. The return of the cholesterol ester after its absence usually indicates the beginning of recovery. In the late stages of obstructive jaundice when extensive liver degeneration often supervenes to close the scene there may also be a drop in the percentage of cholesterol esters.

While the physiologic explanation of these phenomena is at present very much in doubt, the tendency for the percentage of blood esters to drop in liver degeneration discovered by Thannhauser⁷ has been well established as a clinical fact by Epstein⁸.

How much reliance can be placed on cholesterol and cholesterol esters in the diagnosis between obstruction and liver degeneration? They can never be used as a single and specific mode of differentiation in any individual instance. The results always have to be interpreted in the light of the clinical features of the case, when they disagree with these they may lead to doubt but cannot lead to diagnosis. Borderline figures such as 250 for total cholesterol and 40 per cent for cholesterol esters often leave one uncertain. An exceptional case of hepatic degeneration may show high figures. But, on the whole, these determinations are of greater value than any other single test for differentiation. It is always to be remembered that the single estimation must be interpreted with caution and that what is important is rather the tendency in repeated

examinations either for the total cholesterol and cholesterol esters to go up or, on the other hand, for the total cholesterol to diminish (or at least not increase) and the ester fraction to drop disproportionately.

THE GALACTOSE TOLERANCE TEST

Of the numerous so-called liver function tests that have been introduced in the hope that they would be of value in recognizing hepatic degeneration, few have stood the test of clinical trial. In spite of its limitations, perhaps the best is the galactose tolerance test. The levulose test is possibly equally specific for the liver but has the disadvantage that urine excretion cannot be depended on and that a blood sugar curve has to be made. The galactose tolerance test depends on the facts that one of the functions of the liver is to convert galactose into glycogen (and ultimately into dextrose) and that the kidney has practically no threshold for galactose, so that as long as it is circulating in the blood some of it is excreted in the urine. In normal individuals Bauer⁹ determined that when 40 Gm is

Chart 2.—The relationship of blood bilirubin and cholesterol and cholesterol esters

taken into the empty stomach the liver handles it rapidly enough so that only a small amount, usually less than 1 Gm but always less than 3 Gm is excreted in the urine in the following five hours. In liver degeneration usually amounts larger than 3 Gm are excreted. In obstructive jaundice, as a rule, the behavior of the liver is normal in this regard, although in later stages, when the liver cells undergo severe degeneration, the galactose test may also be positive.

As compared with the reports in the literature, my experience with the galactose test is somewhat disappointing. It frequently fails in cases of undoubted liver degeneration. On the other hand, when diabetes can be ruled out, a positive galactose test usually means hepatic degeneration. The excretion of very large amounts, from 6 to 7 Gm or more, is rather conclusive. But the amount is not necessarily a good guide as to the severity of the degeneration. In doubtful cases the test must be repeated. The practical objection to the galactose test is that galactose is rather expensive. The determination of galactose in the urine is done exactly like the quantitative determination for dextrose. The

⁷ Thannhauser S J and Schaber H Klin Wchnschr 5 252 (Feb 12) 1926

⁸ Epstein E. Z. The Cholesterol Partition of the Blood Plasma in Parenchymatous Diseases of the Liver Arch Int Med 47 82 (Jan) 1931

only modification is that, because of the greater reducing power of galactose, it is necessary to multiply the result by 0.7

TYROSINE

Since the recent studies of Lichtman¹⁰ on the significance of tyrosinuria, the detection and estimation of tyrosine in the urine has become of more value in the recognition of liver degeneration than it formerly was. The new test depends on the fact that tyrosinase, a vegetable enzyme derived most conveniently from the potato, is capable of specifically oxidizing tyrosine to produce a dark brown pigment melanin, which lends itself readily to colorimetric estimation. The reaction takes only a few hours as compared with days needed by the former method of detecting tyrosine. It is enormously more delicate than the old methods. It is sensitive enough to detect traces of tyrosine liberated in any autolytic process in the body, such as, for example, breaking down new growths. In jaundice, when tyrosine is present in small amounts in the urine it suggests subacute liver degeneration or a malignant growth. Large amounts are of grave prognostic significance, pointing to acute liver autolysis. With the new method the finding of small amounts of tyrosine is not necessarily of bad prognostic significance, it may occur in cases of catarrhal jaundice. Positive tests have turned out to have considerable diagnostic value. Negative tests mean little.

THE X-RAYS IN DIAGNOSIS

The judicious use of x-rays is of the greatest importance in the diagnosis of silent jaundice. The flat plate of the abdomen, the so-called scout plate, should never be omitted in doubtful cases. It occasionally shows the presence of calcified gallstones.

Among the most difficult cases of painless jaundice in which to make a diagnosis are those of metastatic new growth producing obstruction, partial or complete, by involvement of bile ducts in the hilus or in the liver itself. The diagnosis is usually made only if the primary growth is found, this depends, as a rule, on careful gastro-intestinal studies, especially roentgenograms. The diagnosis is important because this is the one type of obstructive jaundice in which operation is almost always contraindicated. Gastro-intestinal roentgenograms should therefore never be omitted in doubtful cases of jaundice.

SURGICAL JAUNDICE

The management of jaundice cases is dependent entirely on the diagnosis. It would be inappropriate for me to discuss the surgical treatment. The medical man, however, should remember the importance of operating on obstructive jaundice early, if possible within the first two weeks after the onset of obstruction. When one waits too long the damage to general nutrition and especially the increased hemorrhagic diathesis make the outlook for surgical success very much poorer.

In spite of the best available diagnostic efforts there are cases of obstructive jaundice in which the diagnosis before operation is uncertain. In many of these the situation is as follows. The preponderance of evidence points to carcinoma of the head of the pancreas or bile ducts, but obstruction by a calculus blocking the bile duct cannot be entirely ruled out. In these cases it is important to explore early. Though the majority of them turn out to be carcinoma even in these there is often the possibility of palliation with relief of the

jaundice for a year or more, by the performance of an anastomosis between the gallbladder and the stomach.

Before turning to the medical management I wish to say a few words about the hemorrhagic diathesis. This is, of course, of greatest interest to the surgeons because postoperative hemorrhage is the commonest cause of death after operations in jaundice patients. The subject is at present in a very unsatisfactory state because no one has as yet discovered the real mechanism of the hemorrhagic tendency in jaundice. In spite of the enormous amount of research that has been done on the subject there is as yet no single test or combination of tests which will tell beforehand whether a given jaundice patient is likely to bleed after operation or not. In fact, the clinical features of the case help much more in forming this opinion than do any tests. In general, patients with prolonged jaundice (three weeks or more) or with very intense jaundice are more likely to bleed. But this is a rule to which there are many exceptions. Actually, the tendency to bleed depends rather on the extent of liver parenchyma damage than on the jaundice itself. The physical examination of the patient for evidence of bleeding, such as ecchymoses and petechiae, is particularly significant. The production of small ecchymoses by pinching the skin or the production of petechiae at the elbow by the application of a tourniquet (blood pressure cuff) is of serious prognosis. The tests for coagulation time, bleeding time, percentage of fibrinogen in the blood plasma, blood platelets, and shortened sedimentation time of the red blood cells are all of significance as pointing to a hemorrhagic tendency when they give clear cut positive indications. But normal tests in the presence of jaundice are no guaranty of safety.

Preservation of the hepatic parenchyma is the important thing in prevention of hemorrhage. Stress should be laid on rapid diagnosis, early operation and protective diet, such as will be described for the non-operative (hepatic) jaundice cases. Of the many other measures that have been introduced, those which have best stood the test of clinical experience are intravenous dextrose injections, intravenous calcium gluconate injections and blood transfusion. It is important in cases in which hemorrhage is to be feared that these measures be carried out not merely before but especially for a considerable period, perhaps up to two weeks, after operation, as late hemorrhage is a frequent cause of death.

MEDICAL MANAGEMENT

The medical management of jaundice consists essentially of the protection of the liver and the reduction of its metabolic work to the necessary minimum. On account of the multitudinous vital functions of the liver this is an extremely difficult task. Physicians are only commencing to learn the fundamental principles of it. In the selection of the diet the point on which at present there is almost universal agreement is the value of a high carbohydrate diet. This was gradually introduced after the early work of Whipple, Opie and others showed that livers that contained an abundance of glycogen were far less susceptible to certain toxic agents than livers poor in glycogen. Clinical experience with the high carbohydrate diet has been good. As the result of observing over a period of years cases of yellow atrophy of the liver which came to autopsy, Dr. Klemperer has come to the conclusion that since the introduction of carbohydrate forcing the type of cases which end fatally has changed considerably. The patients die at a much later date in the course of the

¹⁰ Lichtman, S. S. and Sobotka, Harry J. *Biol. Chem.* 85:261 (Dec.) 1929. Lichtman, S. S. *Origin and Significance of Tyrosinuria in Disease of the Liver*. *Arch. Int. Med.* 53: 680 (May) 1934.

disease, assuming a subacute rather than an acute type, and they show less complete destruction of the liver parenchyma and much more effort at regeneration than was the case formerly.

The jaundiced patient should receive from 300 to 500 Gm of carbohydrate a day. A considerable part of this should be in the most easily assimilable forms of carbohydrate, such as fruit juices, lactose and dextrose. In most cases there is no reason to believe that digestion by the pancreas is impaired, hence the use of starchy foods is permissible. In cases due to obstruction near the papilla of Vater, the access of pancreatic juice to the duodenum is interrupted and starchy foods should be avoided. In diabetes it is known that insulin favors the deposit of glycogen in the liver, and it has been proposed to administer insulin along with the high carbohydrate diet in jaundice. But except in diabetes there is no good clinical or experimental evidence that this has any advantage, and there are some reasons to think that it may actually do harm.

In patients who do not take their food well or in whom there is reason to believe that absorption is poor, daily intravenous injections of large amounts of dextrose should be carried out. Recently because it is believed that the chemical work of converting lactic acid into glycogen is easier than converting dextrose to glycogen, it has been proposed that 1 per cent sodium lactate be given intravenously for this purpose. This has not yet received enough clinical trial.

Next to the general adoption of the high carbohydrate diet, the avoidance of fat in the diet has become almost universally accepted. The reasons for this are both clinical and experimental. The large amount of fat in the stools of jaundiced patients is evidence that the patient is not absorbing it and that therefore if the fat in the diet does no harm it certainly does no good. Experimentally it has been shown by numerous workers that the presence of a large percentage of fat in the liver cells increases susceptibility to many toxic agents. For these reasons it is desirable to cut the fat in the patient's diet down to the minimum necessary to make the patient's food palatable. In jaundice, most of the fat ingested is not absorbed and is therefore harmless. It is to be regarded rather as something useless. Hence it is not necessary to go to the extreme of refusing the patient all butter, cream and eggs. The important thing is the maintenance of the nutrition of the patient, and if small amounts of these fats are necessary in order to enable the patient to take enough of the more important foods they should be allowed. I stress this point because I have occasionally seen patients put on so one-sided a diet that they were practically in a state of voluntary starvation.

A very large part of the liver's work is concerned with protein metabolism. The liver should be spared as much of this work as possible by the administration of just the minimal amount of protein that the body nutrition requires. This is from 0.7 to 1.0 Gm of protein per kilogram of body weight daily. For an average individual this is generally about 40 to 50 Gm of protein in twenty-four hours. There is probably a difference between proteins. On account of the experimental toxic state that is produced by the administration of meat in dogs with damaged livers there is a suspicion that meat may be harmful in cases of degenerated liver and it should be given sparingly. Preference should be given to proteins derived from vegetable sources, as, for example leguminous foods and to milk, cheese and egg white.

The liver uses the amino acid glycine as a detoxicating agent, coupling it with other substances as in the familiar coupling of glycine with benzoic acid which is then excreted by the kidneys as hippuric acid. It has been suggested that the administration of extra amounts of proteins containing an abundance of glycine (such as gelatin) will help the work of the liver. This seems particularly plausible since the recent work of Quick,¹¹ who has shown that the ability of the liver to perform this protective synthesis is limited by the amount of glycine available. Gelatin is of course an imperfect food lacking certain other essential amino acids. It should therefore not be depended on for too large a proportion of the patient's nitrogen quota but rather a number of grams, perhaps from 5 to 10 Gm, of gelatin a day should be administered to the patient either as part of his food in the shape of sweetened desserts or in powdered form simply as a medicine.

As the object of treatment is to lighten the enormous metabolic labors of the liver, it goes almost without saying that complete rest, mental and physical, is part of the treatment. Drugs seldom play any role in therapy. The liver is the chief chemical detoxicating organ of the body, and drugs only add to the burden of its activities. The course of cathartic treatment with calomel, Carlsbad salt or epsom salt, which was formerly thought essential, probably does not accomplish anything and is likely to interfere with the patient's nutrition. The same may be said of duodenal lavage with magnesium sulphate, a form of therapy that has been advocated by many. It is a rather exhausting form of treatment and interferes with the patient's nutrition. If the papilla of Vater is unobstructed the patient does not need it, as his food will probably act as a sufficient stimulant to cause the emptying of the gallbladder.

The administration of bile salts and other cholagogues has often been advocated. Recently there has been a good deal of doubt about the value of this also. If the liver is suffering from an acute degeneration and the burden of normal secretory activity is too great, it is hard to see how the stimulation of secretion can help. The use of diuretics in acute nephritis has been given up. On the other hand, if obstruction of bile ducts is causing back pressure and thus injuring liver parenchyma it would seem that an increase of bile secretion would only increase the damage. The claims for cholagogues are based chiefly on cases of catarrhal jaundice, which improved rapidly after their administration but as cases of catarrhal jaundice do this so often without any treatment, the observations are not very conclusive. Views have changed largely as the result of better knowledge of the pathologic changes of catarrhal jaundice and its relation to acute yellow atrophy. In the days when it was thought that all catarrhal jaundice was due to mucus obstructing the bile ducts, it seemed logical to try to increase secretion in order to overcome the obstruction. Now from the work of Eppinger,¹² Klemperer¹³ and others it is known that most cases of catarrhal jaundice are merely milder forms of acute hepatic degenerations. It is therefore not thought that the stimulation of secretion is of any importance, but rather that the protection of the damaged liver parenchyma is the vital thing.

CONCLUSIONS

1 The important diagnosis is between medical and surgical jaundice

2 There is no sure method of distinguishing obstruction from suppression of bile (liver cell injury)

3 Determining whether the van den Berg reaction is direct or indirect does not help

4 The icterus index is preferred to the quantitative van den Bergh test for following the curve of bilirubinemia

5 Extremely high blood bilirubin most commonly occurs in hepatic degeneration

6 High percentages of blood cholesterol and cholesterol esters point to obstruction, but on rare occasions they may occur in hepatic degeneration

7 Low percentage of cholesterol esters points to hepatic degeneration. But a normal or even an elevated percentage does not rule out degeneration

8 A positive galactose tolerance test indicates hepatic degeneration. A normal test does not exclude degeneration

9 In jaundice, tyrosine in the urine points to liver degeneration or malignancy. Large amounts point to acute liver autolysis. Its absence has little significance

10 In every doubtful case roentgen examinations should be made, particularly of the gastro-intestinal tract. Gallbladder visualization is of little or no use

11 In surgical jaundice, early operation is important

12 In medical jaundice, protection of liver parenchyma by a suitable diet (and dextrose injections when needed) is the essential thing

ECONOMICAL INTRAVENOUS THERAPY

CARL W. WALTER, M.D.

Harvey Cushing Fellow in Surgery, Peter Bent Brigham Hospital
BOSTON

A safe, inexpensive, readily prepared and instantly available supply of fluid for intravenous injection is a necessity in every hospital. The problem of establishing such a supply in the Peter Bent Brigham Hospital led to the consideration of the difficulties encountered in other hospitals and the investigation of the available commercial solutions. Since this form of therapy is usually an emergency measure, it is essential to have a source of supply over which the hospital has complete control. Use of a container from which fluid can be administered directly prevents delay, decreases the chance of contamination and centers the responsibility for administration of the infusion. The cost of an intravenous technic that has proved successful as judged by the abolition of reaction, availability to the clinician and economy for the hospital has not been reported.

Deleterious physiologic disturbances, ranging from mere elevation of temperature to chills, cyanosis, diarrhea, nausea, vomiting, collapse and even death, following intravenous infusions of saline solution are due to impure water. Various investigators¹ have considered

as the cause of such reactions individual susceptibility, impurities from chemicals, rubber and glassware, the velocity of injection, and the volume, temperature and hydrogen ion concentration of the solution given. The work of Wechselmann,² Seibert³ and Rademaker⁴ established impure water as the chief etiologic agent. Studies conducted in the Peter Bent Brigham Hospital on patients with an adequate cardiac mechanism confirm their observations. Divers concentrations of dextrose in physiologic quantities, ranging from 2 per cent to 25 per cent solutions of dextrose in isotonic saline solution and from 6 per cent to 50 per cent aqueous solutions of dextrose, were administered to patients with no untoward reactions. One liter quantities of 10 per cent dextrose solution were given in ten minutes at temperatures ranging from 20 to 44 C without reaction. As a result, the volume, velocity of injection, temperature and composition of intravenous infusions are left entirely to the discretion of the clinician.

During the year beginning July 1933, 971 consecutive intravenous injections of saline solution, or dextrose in saline solution, were given without an untoward reaction.

A supply of intravenous fluid of good quality can be maintained only by the constant efforts of a responsible person. In this hospital, isotonic saline solution and the apparatus for its administration are prepared in a central supply room by one graduate nurse, supervised by a member of the resident staff. Fresh, singly distilled water⁵ is used and a technic aiming at a chemically pure, sterile product is stressed.

DISTILLATION OF WATER

Distilled water of good quality, evidenced by Carter's test,⁶ can be produced in a still constructed to comply with Rademaker's specifications.^{4b} In this hospital an old still, which had frequently produced contaminated water, was redesigned at small cost. The reconstructed still, which embodies a steam-heated generator of the continuous type produces steam from city water at atmospheric pressure. The generator is equipped with a deconcentrating tube of 20 per cent capacity (Severinghaus⁷), adequate traps for the prevention of entrainment, and a gas outlet of sufficient size to release approximately 10 per cent of the vapor. The rate of boiling is controlled to keep foaming at a minimum. The steam is reduced in a vertical, water-cooled tinned condenser. The condenser and storage tanks are sterilized daily by live steam and washed by distilling into waste for fifteen minutes prior to collecting the distillate.

PREPARATION OF SOLUTIONS

The glassware used in preparing the solutions is washed with hot soapy water and rinsed with tap water. It is then filled with a cleaning fluid composed of 10 per cent potassium dichromate in sulphuric acid (10 per cent) and allowed to stand for at least twelve hours, after which the fluid is poured off and the glassware rinsed thoroughly with eight successive small

7 Severinghaus cited by Rademaker.^{4b}

quantities of distilled water. The glassware is then inverted to drain and must be used within two hours or re-cleaned.

Isotonic saline solution is prepared by adding distilled water to 255 Gm of sodium chloride, previously weighed out in a clean flask, until a net weight of 1.192 Gm has been reached. The flask is stoppered with a

Both saline and dextrose solutions may be kept at room temperature indefinitely. With planning, however, no solution need be more than thirty days old.

PREPARATION OF APPARATUS FOR INTRA- VENOUS INJECTION

To prevent contamination of nonpyrogenic intravenous fluid, the utmost cleanliness of the inside of the tubing, syringes and needles is essential. New rubber tubing and stoppers are treated by a modification of Stokes's¹ technique, being soaked in a 10 per cent

Fig 1—Apparatus for intravenous injection in which the fluid is administered directly from the original container

clean rubber stopper and shaken until solution is attained. This stock solution is filtered directly into a 300 cc buret through a Jena fritted glass filter. Twenty-five cubic centimeters of the crystal clear filtrate, containing 6.4 Gm of sodium chloride, is added to approximately 600 cc of distilled water in a graduated cylinder and the volume adjusted to 770 cc. The contents of the cylinder are then poured directly into a 1 liter flask without filtering. The 2 liter flask is filled by diluting 50 cc of the stock solution to 1.520 cc. A clean rubber stopper is held in place loosely by a paper flask hood secured with a rubber band. After the flask has been sterilized for twenty minutes at 250 F the rubber stopper is pushed into the mouth of the flask, the paper hood removed and the skirt of the stopper turned down, giving a permanent sterile seal.

The dextrose solution is made by adding chemically pure anhydrous dextrose slowly, with constant stirring to boiling distilled water in a granite-ware container kept especially for this purpose. The solution is diluted with distilled water to produce a 50 per cent solution which is doubly filtered into 50 cc screw-cap bottles the filtrate being returned to the funnel until a crystal clear liquid is obtained. The bottles are capped and autoclaved for fifteen minutes at 250 F.

solution of sodium hydroxide for twenty-four hours, rinsed thoroughly in running tap water and boiled in a 1 per cent solution of hydrochloric acid for one hour. The process is completed by rinsing with distilled water until the rinse water tests neutral to litmus paper, and by drying with the aid of suction. Care must be taken that the solutions run through the tubing continually, otherwise the inner surface, which comes in contact with the intravenous fluid, will not be properly cleaned.

Fig 2—The parts of the apparatus, their cost and source when one particular brand is desirable is given in table 1

After use the apparatus is washed with cold water and returned to the supply room where it is cleansed immediately prior to sterilization. All the parts are separated and washed thoroughly with hot soapy water and rinsed in cold tap water for thirty minutes. The inside of the parts must be thoroughly cleaned. The capillary valves and stoppers are wrapped in a single layer of gauze and boiled with the tubing in a 0.5 per

cent solution of sodium hydroxide for forty-five minutes, the alkali running through the tubing continually during the boiling. After the parts are allowed to cool in the solution, the stoppers and valves are rinsed six times with distilled water and distilled water is run through the tubing for thirty minutes. Everything is dried thoroughly on a clean, dust-free sheet with the aid of suction. The Kaufmann syringes and needles are washed in hot soapy water and rinsed thoroughly in distilled water, then dried with acetone and suction. The sets are assembled as illustrated in figure 1, the needles being placed in a 10 by 75 mm test tube plugged with loose cotton. This equipment is placed in

cost \$0.162 each when Kaufmann syringes were used. The substitution of simple glass adapters in place of the syringes would reduce breakage so that sets would cost \$0.095 each, a saving of 41 per cent. These costs were possible even though the monthly demand varied from twenty-nine sets and thirty-eight liters of saline solution to 157 sets and 164 liters of saline solution. Sterile dextrose solution, in 25 Gm bottles, cost \$0.025 each for 5,184 units. The percentage cost charged against labor and supplies is listed in table 2.

The comparative cost of commercial and hospital-made solutions is brought out in table 3, based on charges in Boston.

TABLE 2—Percentage of Costs

Item	Per Cent of Cost
Labor of graduate nurse	40.8
Breakage of needles and syringes	21.0
Chemicals	19.2
Breakage of glassware	6.0
Depreciation of rubber	1.0
Miscellaneous	2.5

a clean aluminum pan wrapped in a double-thickness muslin sterilizing cover and then autoclaved for fifteen minutes at 250 F. If the sets are not used within fourteen days they are considered dirty and reclaimed. Much extra work may be avoided by using the sets in rotation.

COST OF INTRAVENOUS THERAPY

An investigation of the cost of the system just outlined has been carried on during the last thirteen months. All items of expense including labor, chemicals, deterioration of rubber and breakage of glassware, have been considered, with the exception of the cost of distillation, sterilization and depreciation of stable equipment. Since the still and autoclaves are run continuously to provide distilled water and sterile goods for the remainder of the hospital it is felt that these items might be considered a negligible expense. The accounting system in use in the hospital does not consider the depreciation of small articles of equipment, their cost being charged only when replacement is required. At the end of the thirteen months period all the equipment was inspected and appropriate charges made for the replacement of worn articles, so that a fair maintenance cost has been established.

TABLE 3—Comparison of the Cost of Hospital-Made and Commercial Solutions

Solution	Hospital Made \$0.09	Commercial Cost (14 Gross Lots) \$0.49	Per Cent Saved
Isotonic saline solution 1,000 cc.			81.5
10 per cent dextrose in saline solution, 1,000 cc.	0.172	1.21	85.7
50 per cent dextrose 50 cc.	0.025	0.20	87.5
Cost of new sterile intravenous tube and needle set (glass adapter type)	1.07	2.60	58.8
Cost of recleaning and sterilizing sets	0.063		

The cost of the original equipment and its source, when one particular brand has been found more desirable, is given in table 1. The average cost of 1,123 injections, including the cost of preparing the saline solution and of cleansing and maintaining the equipment was \$0.266 each. The average quantity of saline solution used was 1,150 cc, the extremes being 200 cc and 40,000 cc. The isotonic saline solution itself cost \$0.089 per liter. The cost of a 1 liter infusion of 10 per cent dextrose, including solution and apparatus, was \$0.335. Cleaning the apparatus for injection, breakage and deterioration of rubber for 1,123 units

SUMMARY

A technique for the preparation of safe instantly available intravenous fluid administered from the original container and prepared under the complete control of the hospital resulted in a net saving of from 81 to 87 per cent over comparable commercial solutions, with \$0.266 as the average cost of 1,123 intravenous injections of saline solution. The cost of 1 liter of isotonic saline solution was \$0.089 and of 1 liter of 10 per cent dextrose in saline solution was \$0.172.

721 Huntington Avenue

PURPURA AS A SYMPTOM IN PEDIATRIC PRACTICE

H. G. PONCHER, M.D.

CHICAGO

That purpura is a symptom of diverse causation was appreciated since its first description. In 1735 Werlhof recognized a singular disease picture among a large number of diseases characterized by purpura and called it morbus maculosus haemorrhagicus. Today the disease is known as purpura haemorrhagica, Werlhof's disease, or essential thrombocytopenic purpura. It is a chronic intermittent constitutional condition, characterized by the occurrence of purpura or mucous membrane hemorrhages in previously healthy persons without any apparent cause. The disease as it is recognized today is certainly different clinically from that which Werlhof described. His case was an acute manifestation, occurring in a girl at the time of puberty. Werlhof's original description was as follows:

A grown, strong girl recently got severe nasal hemorrhages at the time of menstruation without known cause. There flowed bright colored but foul smelling blood and at the same time a bloody sputum with thick, very dark blood. At the same time there appeared on the arm spots, partly black, partly violet, blue or purple-red, as one often sees them in malignant smallpox. The rapid loss of strength and the fact that I recognized this as a rare disease with hemorrhages, well known to me forbade a venesection. The hemorrhages from the nose and mouth continued without stopping. The fainting spells and the cold extremities associated with a weak and rapid pulse, demanded an effective intervention, especially since the number of spots multiplied and the whole region of both eyes, the nose and the skin of the mouth and chin were covered with a livid black color. Generally the nasal hemorrhages stopped, the flow of saliva diminished and stopped on the following day, the fainting spells did not return. The spots daily took on a more reddish and then a pale color and disappeared on the seventh day, at which time the pulse had also again reached its normal rate. The strength returned in step with the recovery, even though menstruation did not come at the regular time.

Today the chronic intermittent form is considered the prototype of Werlhof's disease. I greatly doubt

whether the acute form belongs here. The individual attacks in this disease, however, have a great similarity to the disease described by Werlhof. Many years later Willan (1808) described a case of purpura occurring in a woman, aged 36. There was a course of abdominal colic, vomiting and bloody diarrhea, painful and swollen joints and a variety of skin lesions, including purpura, urticarial wheals and angioneurotic edema. Other cases presenting this syndrome in part or in its entirety were reported by other investigators, who also differentiated it from Werlhof's disease. In 1832 Schönlein emphasized this clinical picture under the name of *peliosis rheumatica*, stressed the joint symptoms, and warned against confusing it with Werlhof's disease.

Henoch's report in 1874 revived the interest in this syndrome by elucidating the gastro-intestinal complications. He, too, distinguished such cases from those reported by Werlhof but doubted its rheumatic etiology. At a later date he noted the presence of hematuria and described the complete clinical picture as it is known today. Henoch also recognized purpura complicating infectious diseases and endocarditis, as witnessed by his admonition "you should therefore never fail to examine the heart in febrile purpura." His conception regarding the pathogenesis of other types of purpura is also interesting. In discussing the group which develop independently of a febrile general disease or endocarditis he says

Unfortunately we know nothing of the nature of these morbid conditions, or even of the anatomic causes of the numerous hemorrhages. The old view that it is due to a vice in the composition of the blood can be proved neither by chemical nor by microscopic examination. Nor has the former theory of diminished coagulability of the fibrin been confirmed, and it was therefore natural that the small blood vessels should be held responsible. As the hemorrhage could occur from rupture of the vessels as well as from migration of the red globules through their walls, abnormal friability of the latter was thought of, and, in fact microscopic changes of the small arteries and capillaries which are calculated to produce such a result, have been described by various investigators. Although the occurrence of these changes cannot be denied I think that they can be taken into consideration in severe and fatal cases alone. If we remember how suddenly morbus maculosus sometimes develops and how quickly it may disappear, the assumption of any considerable structural changes in the vessels is hardly allowable in such cases and this very fact proves that we have to deal with various conditions in this disease. The severe form depends perhaps on the changes in the small vessels, while in milder cases we may think of a vasomotor neurosis, which gives rise to stasis of blood rupture of the walls of the vessels or migration of red blood globules from paralytic dilatation of the smallest vessels. The complication with slight edema in a series of cases also favors this hypothesis.

These views are interesting with respect to the later advances and might easily be mistaken for a contemporary discussion of purpura. Subsequently writers reported cases representing purpura as a symptom and eventually two schools of thought arose.

1 Those who believed that all purpuric diseases were members of one group and were merely clinical variants of the same hemorrhagic diathesis and belonged together etiologically.

2 Those who believed that the various types of purpura were distinct entities.

In 1881 Brohm reported two cases of Werlhof's disease in which the cells now known as platelets were diminished, and this was correlated with purpuric manifestations. His observation however failed to excite any interest. Two years later Kraus of Brohm's clinic called attention to Brohm's observation and reem-

phasized the possible correlation between platelets and purpura. The diminution in platelets was then stressed as the most characteristic manifestation in Werlhof's disease, although even at this early date Denys, a Belgian pathologist, pointed out that thrombopenia is only a symptom and occurred in other diseases besides Werlhof's disease. However, the subject had just been removed from a period of rationalization and the platelet hypothesis was looked on as a step toward the solution of the etiology of purpura. When Duke published his work in 1910-1912, the importance of thrombopenia in purpuric diseases received another impetus. Duke emphasized that when platelets reached a low level the bleeding time was increased, and that this was an important mechanism in Werlhof's disease.

Clinicians began to recognize other diseases associated with thrombopenia, but in such cases the reduction of platelets appeared to be secondary to the original disease. Classifications of purpura then arose which were based on whether thrombopenia was primary or secondary, or whether platelet involvement was present or not. Werlhof's disease was characterized as essential thrombopenia, and the other diseases associated with purpura and a reduction of platelets were spoken of as symptomatic thrombopenic purpura. Conditions like the Schönlein-Henoch syndrome were described as symptomatic nonthrombopenic purpura.

Within recent years, however, the mechanism of purpura has been subjected to closer scrutiny. One is no longer satisfied to speak of all cases of purpura as hemorrhagic diathesis but attempts to understand the various purpuric conditions by applying anatomic and physiologic methods. Unfortunately, it can hardly be stated that these methods have been entirely successful, but while they have obvious limitations as a means of causal analysis they give an insight in the mechanism by which symptoms may be evolved. These facts considered in the light of sound clinical observation and careful pathologic study have yielded information leading closer to rational thinking on the subject. It is now generally agreed that the two most important factors concerned with the production of purpura are alteration in the number and possibly the function of the blood platelets and changes in function and structure of the blood vessels.

BLOOD PLATELETS IN PURPURA

It is generally accepted that the blood platelets are the third formed element of the blood and that they reach the circulation by a process of budding off from the megakaryocyte in the bone marrow. They are capable of liberating a thromboplastic substance when they rupture, and this property is important in thrombus formation and clotting. Normally they are present in the circulating blood in amounts varying from 250,000 to 400,000 per cubic millimeter or about one platelet for every fifteen or twenty red cells. When they reach a very low level the bleeding time is increased, there is deficient clot retraction and stasis or trauma may produce capillary hemorrhages. Because of these facts, thrombopenia is used as one explanation for the development of purpura. The following are some of the premises on which this idea is based.

1 The closure of a bleeding wound occurs by means of a platelet thrombus.

2 Experimentally one can associate purpuric manifestations following platelet reduction.

3 Clinically one often finds the platelets reduced in certain diseases that have purpuric or hemorrhagic manifestations.

The question arises: How intimate is the relationship between deficiency of the platelets and the tendency to purpura and hemorrhage? In most of the work in which platelets have been reduced, experimental agents have been used which also affect the endothelium of the blood vessels (diphtheria toxin, benzene and beef serum). On the other hand, when agents or methods have been used to affect only the platelets, no purpura has been produced. Bedson's experiments illustrate this point vividly. Bedson was able to prepare an anti-platelet serum injection of which resulted in complete absence of platelets yet no purpura or hemorrhage resulted. But if subsequently a second serum was injected, designed to act on the endothelium of the vessels, purpura and spontaneous hemorrhages were noted. Other investigators have corroborated this by using other methods to reduce platelets and like Bedson's experience some other factor besides thrombopenia was found to be necessary.

There are also numerous clinical observations that question the absolute relationship of thrombopenia and purpura. I have observed spontaneous hemorrhages and purpura when the platelet count was high and no hemorrhages and purpura when the platelet count was low. Also there is a decided lack of agreement between bleeding time and platelet count. If one takes the bleeding time in various parts of the body with the same puncture technique when platelets are reduced one will usually obtain figures that vary within wide limits. Were the bleeding time solely dependent on platelet reduction, this would be a difficult phenomenon to interpret. Numerous examples illustrating this point can be cited.

Finally, the results following splenectomy in Werlhof's disease have led to the premise that thrombopenia is the cause of the symptoms. Splenectomy was first advised because Kaznelson believed that the spleen was removing excessive numbers of platelets from circulation while others felt that the spleen exerted a myelotoxic influence and depressed the platelets at the site of their formation. There is absolutely no reliable proof for either premise in spite of the well known beneficial effects of splenectomy in cases of Werlhof's disease. Platelet counts on the blood from the splenic artery and splenic vein are often cited to prove the thrombocytolytic action of the spleen in Werlhof's disease. The same values may be obtained in individuals without Werlhof's disease. And, finally, there is the fact that the level of the platelet count, after splenectomy does not always parallel the clinical improvement. While there is a rise in platelets immediately after the operation the platelet count may again go down to the preoperative level and yet the patient often remains symptom free. Bedson has come to the conclusion, as a result of his experimental studies, that the blood vessels of spleen-exstirpated animals present a particular resistance. This experimental work on the effect of resistance of blood vessels following splenectomy is promising but also needs further study.

The apparent conflicting data that I have briefly summarized force the assumption of some other factor besides thrombopenia in order to explain spontaneous purpura and hemorrhage. The facts appear to be that platelets have a protective action against the spontaneous occurrence of purpura and hemorrhage but their absence is not the direct cause for such bleeding. The primary cause must be another factor. When this

factor is absent hemorrhage will not occur whether platelets are reduced or not. When this factor is present, the function of platelets is to act as a protection and condition the severity of the bleeding. This may be achieved partly or completely. The vascular factor will fulfil this role, but one must not go too far in looking at thrombopenia as a secondary matter. The regularity with which thrombopenia is found in Werlhof's disease and other diseases associated with purpura indicates that thrombopenia is probably as important a symptom as capillary alteration. The connection between capillary damage and thrombopenia may be reciprocal and the symptoms may follow a common insult.

The insults that may lead to purpura and hemorrhage are so numerous and their effects so diverse that one can say nothing uniform at the present time regarding their pathogenesis. All are familiar with the conventional classifications of purpura, so that it will not be necessary to discuss that here. No classification, however, seems to exhaust the possibilities of nature. In those diseases in which purpura is obviously symptomatic of vascular injury or bone marrow damage, the pathogenesis is understandable. Therefore I do not believe it will be necessary to discuss the purpuric symptoms following scurvy, infectious diseases, toxic agents, endocrine disorders, diseases of the blood forming organs, and cachectic states. In these conditions purpura is a well recognized manifestation and its genesis can be traced. Eliminating Werlhof's disease from the discussion leaves the Henoch-Schönlein syndrome.

THE HENOCH-SCHÖNLEIN SYNDROME

In my opinion this condition appears in pediatric practice more frequently than is recognized and its clinical manifestations are so diverse that there is failure to get a comprehensive grasp of the basic mechanism at work. Its diversity may be due to the fact that etiologically one is not dealing with a disease unit. There is fair clinical evidence that the syndrome is conditioned by the constitution and reaction of the organism and that the same functional or anatomic changes are not always produced in every case. To speak of this group as anaphylactoid purpura or capillary toxicosis is to ignore its variable clinical picture. Undoubtedly many cases are found in allergic individuals or in those in whom capillary toxicosis may be surmised but the etiology is by no means uniform.

The occurrence of the purpura in this syndrome is merely as a facultative symptom and it does not represent the essential part of the underlying pathologic condition. In Werlhof's disease the purpura and mucous membrane hemorrhage dominate the clinical picture and the patient appears to be well except for this. If symptoms develop in patients with Werlhof's disease they are attributable to the location of the purpura or hemorrhage or to the anemia developing from blood loss. On the other hand, the patient with the Schönlein-Henoch syndrome may or may not have purpura with every attack, and definite visceral manifestation not related directly to purpura ushers in an attack. This was appreciated quite early in the history of this syndrome but because of our propensity for classification the Schönlein-Henoch syndrome has always been dominated by its most variable symptom, purpura. Variation in the type of cutaneous changes and variability of the visceral manifestations occur

often enough in individual cases to justify the assumption that in such cases one is dealing with some general process and not with a static dysfunction

There is enough experimental and clinical evidence of this disturbance to warrant a broader clinical perspective and not the mere grouping under the classification of nonthrombopenic purpura. Henoch, in his first descriptions, as already noted, called attention to the possibility of a vasomotor neurosis underlying the change, and Sir William Osler grouped such cases under the title of "Visceral Complications of the Erythema Group." From the years 1895 to 1914 Osler published a series of papers calling attention to the fact that various skin lesions of the erythema multiforme group occur in association with general disturbances and that the exact form of skin lesion or visceral manifestation may vary from time to time in the same individual.

In Werlhof's disease the main cause of the purpura and hemorrhage seemed to be assigned to a coordinated dysfunction of platelets and a local vascular factor. This cannot be postulated for the present group under discussion. Platelet counts are normal, as are the bleeding time and clot retraction. The formed elements and plasma constituents concerned with the clotting process appear to be normal in every respect. The underlying cause in this group appears to reside in the small vessels, resulting in a focal change. Comparable symptoms appear after the ingestion of certain food in allergic individuals or after the injection of serum or the ingestion of drugs to which the patient may have an idiosyncrasy, but there is no justification for speaking for the entire group as anaphylactoid.

Similarly in the usual classifications there is a tendency to pick out cases with like features and group them as clinical entities, such as Schönlein's purpura when associated with joint symptoms, and as Henoch's purpura when associated with gastro-intestinal symptoms. However, if one carefully studies such cases one will see that attacks will recur with such a variation in skin lesions and visceral manifestations so as to overthrow completely the grouping to which the first attack was assigned.

Henry Christian stated the problem exactly when he wrote

It seems to me that the subject is somewhat clarified by looking on all of these patients as having a common focal disturbance that allows for various types of exudation giving skin lesions of different appearance depending on the relative proportions of serum, red cells, white cells and tissue reaction and visceral lesions of different sorts depending on the site and character of the visceral vascular lesion. This conception would explain the varying skin lesions, now with arthritic symptoms, now with abdominal pain, and now with hematuria etc. in all sorts of combinations.

The mechanism of the symptoms is usually assigned to vascular dilatation and exudation sequelae of serum or formed elements. Thus intestinal colic is explained on the basis of exudation of serum or blood in the bowel wall. Operation has been performed in cases showing such changes as acute surgical emergencies and the foregoing conditions have been found. Incidentally, one often reads of the necessity of differentiating such cases from intussusception, but intussusception may occur in such cases and should be treated as an acute surgical emergency when classic signs are present. Serous exudate in the knee joints is used to explain the arthralgia and pains in the legs.

VASCULAR DILATATION AND CAPILLARY PERMEABILITY

The question naturally arises, What objective evidence is there for vascular dilatation and how are vascular dilatation and increased permeability brought about? Müller observed that the skin capillaries in cases of the Schönlein-Henoch syndrome are dilated, lengthened and distorted. This is not found in Werlhof's disease. Frank believes that the condition is a transudative-exudative diathesis with a facultative hemorrhagic character, and purpura in the Henoch-Schönlein syndrome is only a secondary manifestation, which develops in a primary erythematous or urticarial lesion. The basis of the clinical manifestations, whether in the skin, gastro-intestinal tract, kidneys or joints, is an alteration of capillary function, which may produce all the transitional stages between hyperemia, edema, purpura and a true inflammatory response. Clinically, all transitions are seen from melena to a true colitis, from albuminuria and hematuria to a true hemorrhagic nephritis, and from arthralgia to a true serous involvement of the knee joint.

Regarding the mechanism of vascular dilatation and changed permeability, the experiments of Dale and Laidlaw are illuminating. These investigators injected a cat intravenously with histamine and produced capillary changes analogous to those seen clinically in the Schönlein-Henoch syndrome. They were therefore of the opinion that histamine produces a condition resembling traumatic or anaphylactic shock, with marked accumulation of blood in the peripheral capillaries and increased viscosity of the blood due to leakage of the plasma from the capillaries into the tissues. If the vessel permeability is carried still farther, diapedesis of cellular elements may take place. Serum sickness, as well as histamine injection also presents points of similarity to the clinical picture of the Schönlein-Henoch syndrome. Cases of food allergy presenting a comparable picture have been seen by many clinicians and in spite of negative skin tests often the removal of certain articles from the diet results in a relief of symptoms. Glanzmann concludes that the Schönlein-Henoch syndrome is an anaphylactic phenomenon on the basis of such data, but it is his opinion that the initiating factor is a foreign protein derived from bacterial infection. The introduction of this foreign protein causes the liberation of an anaphylatoxin, which acts as a capillary poison by affecting the vasomotor mechanism.

Unquestionably there are instances of purpura that fit the experimental and clinical facts I have just mentioned, but such a sweeping generalization for all cases presenting the Schönlein-Henoch syndrome seems ungrounded in fact. It seems more reasonable to assume that since a derangement in the vascular permeability is the underlying dysfunction, anything which can produce this derangement can call forth the syndrome in some or all of its phases. It is my belief, however, that the present account of the pathogenesis is only part of the story. It is true that patients with purpura of this type do show capillary changes like those described by Müller, during their attacks, and many of the clinical manifestations are associated with vascular dilatation and increased permeability. Yet these changes do not explain the early symptoms presented by patients with the Schönlein-Henoch syndrome.

While there is ample evidence of vascular dilatation and increased permeability of the vessels in the fully developed case, the question should naturally arise as

to how such changes are initiated. To ignore this question is to miss a very important clinical aspect of the patient and a very important mechanism by which many if not all the symptoms may be produced. I do not mean to imply, however, that this very complex clinical picture is as simple as I shall outline it. The human body has at its command such a variety of reactions that in many instances standardized descriptions are merely half truths. If, however, one studies the patient and then his symptoms, one is more likely to understand his illness.

Often these children are pale in appearance and yet one is surprised when one examines the hemoglobin content of their blood. They are seldom markedly anemic and the implication is that the prior is of angiospastic origin. At another time such a patient may be flushed and appear plethoric. Minor disturbances of one sort or another characterize this group, varying from complaints related to the gastro-intestinal tract to vague pains in the legs and headaches, symptoms that are seemingly intangible and common in every household. How much of this falls within the normal is not known. When however such symptoms increase in frequency and magnitude they begin to be a source of concern to the parents who, if economic conditions permit, consult their physicians. A routine examination usually fails to establish definitely the underlying cause of the complaints although the parents seldom leave the office without some definite advice which the physician did not learn as a result of his scientific training. Such patients are seldom seen in institutions or dispensaries of charity clinics early in their life history. They are seen only when the symptoms persist long enough to produce a definite dysfunction. One of the clinical manifestations may be the Schönlein-Henoch syndrome but more often the symptomatology remains obscure with indefinite disabilities, vague pains and transient symptoms which are referred to various organs. These individuals range from the pole of normality and organic well being through periods when there is subjective perception of organic discomfort and objectively demonstrable disease.

In the average case the basic mechanism is difficult to surmise. The disease is usually of short duration and the patients are seldom brought in early. The self-limited character of the attacks further adds to the difficulty. It is only when such attacks recur or persist that one can get some idea of the underlying mechanism. The onset is usually characterized by headache, dizziness, anorexia, lassitude and pains in the legs or abdomen. At this time no exudative features are present but, instead if one looks at the skin capillaries by means of a capillary microscope one will usually find them contracted in spasm. Later, however, varying from a few hours to a day, the classic picture of the syndrome develops.

It is customary to regard the blood supply to tissues as uniformly adequate unless gross pathologic disturbances exist. The assumption is made that in all normal individuals all tissues are adequately supplied. Clinically, the possibility of regional or organ inadequacy of vascular function is seldom considered unless the clinical manifestations are obvious, as in Raynaud's disease or related disturbances. As a matter of fact, variation in oxygen supply is probably one of the most common events and dysfunction or inadequacy of the mechanism that has to do with oxygen supply is probably fundamentally related to a large number of clinical symptoms.

This phase of the subject is involved and, in order to obtain an accurate picture of what is constantly going on, a large number of reactions must be assessed. However, there is reason to believe that consideration of the functional and organic changes of the capillaries in various parts of the body will lead to the focal point of the whole problem. The normal rhythm of blood supply to the tissues is maintained by stimuli derived from tissue metabolism, the vasomotor mechanism, and endocrine secretions. When this rhythm is altered and there are periods of prolonged vasoconstriction and tissue anoxia, the subsequent phase of correction by vasodilatation may be attended by symptoms. Eugene Landis of Philadelphia has recently shown, however, that capillary dilatation is not accompanied by increased permeability, as measured by protein loss, unless there is oxygen lack. Thus, in spite of the theoretical stretching of the walls of the smaller vessels, permeability does not definitely change until the endothelium is altered.

PERMEABILITY OF ENDOTHELIUM

The agents that alter the endothelium may be as varied as the etiologic factors that invoke the Schönlein-Henoch syndrome. Whether the endothelium will be functionally altered or structurally changed appears to be a matter of degree with which the various agents act and the state of the endothelium at the time the various factors are operative. Likewise, whether increased permeability will result directly by primary endothelial damage or secondarily through the mechanism of anoxia will depend on the intensity of the stimulus and the resistance of the endothelium. The previous state of the endothelium probably plays an important role in conditioning the response. Thus, Tidy quotes a case in which an elastic bandage was advised for a pain in the knee. Subsequently purpuric manifestations developed in every part of the skin surface except under the area of skin covered by the elastic bandage.

In general, the factors concerned with the permeability of the endothelium may be enumerated as follows:

1 *Hereditary Factors*—It has often been observed that the same stimulus applied to a group of normal individuals will result in many types of responses with regard to endothelial permeability. There is also a distinct tendency of members of the same family to show similar reactions.

2 *Environmental Factors*—It would be of interest to know the incidence of the Schönlein-Henoch syndrome according to geographic distribution, as there is a distinct tendency for patients to have their attacks in the spring, fall and winter months. Whether the changes are conditioned by meteorological influences, presence or absence of adequate exposure to ultraviolet rays, or other factors inherent in a given environment is not known definitely. William Petersen, however, has shown a definite correlation between permeability and meteorological changes in his recent monograph on "The Patient and the Weather."

3 *Allergic Factors*—These may be hereditary or acquired. The hereditary group is exemplified by the allergic individuals who respond with symptoms of increased permeability to substances ingested or applied externally. Thus there is definite evidence of the familial incidence of allergy to food and drugs. Likewise the individual may acquire allergy, as for example by repeated injection of horse serum, and react in the same manner.

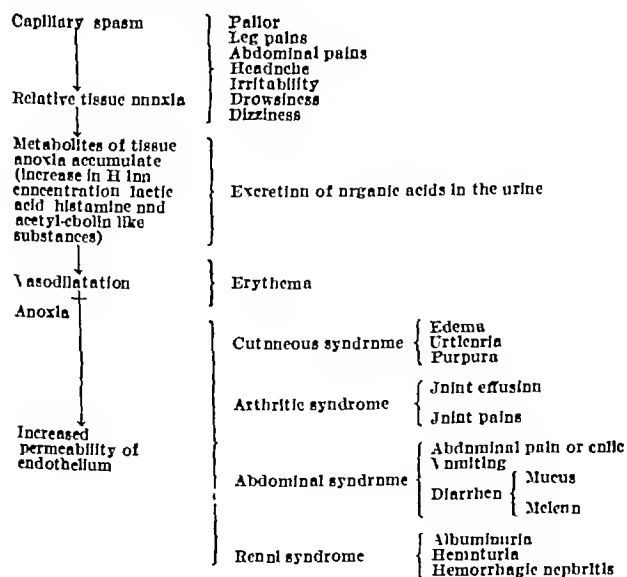

4 *Vasomotor Factors*—The fact that many allergic reactions cannot be passively transferred indicates that

changes in permeability may be initiated through the mediation of the vasomotor system. This is represented by those individuals with dermatographism, angioneurotic edemas and allergy to cold, heat and sunlight.

5 Endocrine Factors—While very little is accurately known of these factors, the increased permeability during the menstrual cycle is familiar. Edema, urticaria and purpura are often observed. Likewise, the increase in permeability in hyperthyroidism and the decrease in hypothyroidism has been demonstrated. Petersen has shown that the blister time is decreased in hyperthyroidism and increased in hypothyroidism. Both conditions may be returned to normal values by appropriate treatment.

6 Hygienic and Dietary Factors—The effect of fatigue on permeability is well known, as are the effects of malnutrition. Since the discovery of the chemical nature of vitamin C it is now possible to measure quantitatively the amount of deficiency required to produce endothelial alteration. Recent work indicates that when the amount of cevitamic acid excreted in the urine drops below 4 mg. in twenty-four hours, permeability of the endothelium is increased and this can be definitely demonstrated by the capillary fragility test.

7 Oxygen Lack—Whether tissue anoxia is produced by general or local factors, the permeability of the endothelium is usually altered. The two factors may be at work simultaneously or they may function independently. Anoxemia resulting from severe anemia, stasis and other factors may reduce the amount of oxygen that is supplied to the endothelial cells. Capillary spasm is an important local factor in the production of tissue anoxia. The spasm may result from the effect of toxic agents, alkalosis, disturbed ionic balance resulting from either an increased potassium or sodium or decreased calcium or magnesium content of the serum, and vasomotor imbalance resulting in unduly prolonged vasoconstriction.

While probably all the factors mentioned may play a part in the etiology in the Schönlein-Henoch syndrome, the sequence of events may be graphically presented, as above, as one possible mechanism by which the classic clinical picture may be evolved.

The rapidity with which some changes in the permeability occur seems to point to the possibility that

capillary spasm with resultant anoxia is not always a necessary stage and that direct endothelial damage may sometimes be the underlying mechanism. In other words, each case must be carefully studied if a comprehensive understanding of the pathogenesis is to be obtained.

In this discussion I have attempted to present the subject of purpura as a symptom in the practice of pediatrics. The more carefully one studies patients with purpura, the more one realizes that only a broad clinical perspective will lead to an understanding of its diverse causation and pathogenesis. While one of the most tragic things in medicine is the slaying of a beautiful theory by an ugly fact, it is justifiable "homicide," for, after all, facts are the basis for rational thinking.

THE SYNDROME OF THE ANTERIOR CHOROIDAL ARTERY

REPORT OF A CASE

ALBERT T. STEEGMANN, M.D.

AND

DAVID J. ROBERTS, M.D.

CLEVELAND

The syndrome of the anterior choroidal artery consists of a hemiplegia, hemianesthesia and hemianopia contralateral to the side of the lesion in the central nervous system. The syndrome is quite rare, and reports in the literature, especially in the English literature, are meager. Abbie¹ has reported a case from the service of Dr. Ivy McKenzie and has contributed excellent anatomic studies on the distribution of the vessel. Proved cases of occlusion of the anterior choroidal artery have also been reported by Kolisko² (two cases), Ley,³ Schiff-Wertheimer⁴ and Poppi.⁵ No anatomic studies were made in the case reported by Austregesilo and Borges Fortes.⁶

The areas of the brain supplied by the anterior choroidal artery have been investigated by Beevor,⁷ Fox,⁸ Abbie⁹ and others. The artery arises directly from the intracranial portion of the internal carotid artery lateral to the origin of the posterior communicating artery and medial to the origin of the middle cerebral artery. It crosses beneath the optic tract medially and in its posterior course sends branches through the optic tract into the internal capsular region and branches laterally to the amygdaloid nucleus and to the choroid plexus in the temporal horn of the lateral ventricle. The terminal branches pass posteriorly to the region of the lateral geniculate body. Here they join

branches from the posterior choroidal and the posterior cerebral arteries. Abbie has emphasized that the terminal field of supply is not only the least affected by anatomic variations but also of the greatest clinical importance. This terminal field of distribution includes the posterior two thirds of the posterior limb of the internal capsule, most of the globus pallidus, the lateral aspect of the external geniculate body, the beginning of the optic radiations and the middle third of the crus cerebri. It is easily understood from this distribution that the involvement of the posterior portion of the internal capsule can, if damaged, produce contralateral hemiplegia and hemianesthesia. Likewise the involvement of the optic radiations and lateral geniculate body accounts for the hemianopia to the opposite side. The rest of the field of distribution is overlapped by other vessels and does not affect structures that give rise to clinical symptoms. A pathologic process of any type that causes an occlusion of the vessel giving rise to an ischemic softening in the terminal field offers the ideal mode of production of the syndrome. It may occur as a part of a spontaneous subarachnoid hemorrhage in a young person illustrated by the following case.

History—J. S., a schoolboy, aged 17 years, admitted to the Cleveland City Hospital Aug. 16, 1933, because of paralysis of

Restriction of the visual fields with a homonymous hemianopia to the left. A 2 mm. white disk was used as a test object.

the left side, had been seized with a sudden severe cutting pain in the right eye two days before, while playing ball in the street. The pain was so severe that he had to lie down on the grass. In a few moments he went home, a short distance, and on arrival noticed that the left arm was weak. After lying down for about an hour he attempted to walk but fell to the floor because of weakness of the left leg. On attempting further activity he became dizzy, nauseated and unconscious for a short time. This was followed by projectile vomiting. The family physician was called and on examination discovered a left hemiplegia and hemianesthesia. He sent the patient to the hospital.

There was no history of any severe illnesses. At the age of 2 years the patient fell out of a second story window but made an uneventful recovery in a local hospital. When he was 10 years old a sudden severe pain developed in the right eye similar to that in the present illness. This was followed by severe headache but no other symptoms, and recovery occurred in a few days. Eight weeks before the present illness he received a hard fall from his bicycle and struck his face over the right malar bone. After this he had a severe headache but no pain in the eye.

The family history was essentially unimportant.

Physical Examination—The patient was well developed and nourished but was obviously very sick. He appeared apathetic and moderately drowsy. He complained of a severe headache and pain in the right eye. The neck was rigid with evident signs of meningeal irritation. The temperature varied between

39 C (102.2 F.) and 40 C (104 F.). Physical changes exclusive of the central nervous system were not remarkable. The left arm and leg were very weak, and there was a left supra-nuclear type of facial palsy. The tendon reflexes on the left side were in shock and abdominal or cremasteric reflexes on that side could not be obtained. Plantar flexion was weak when the left sole was stroked, but the Babinski sign was not present. The pupils reacted to light and there was no choking of the optic disks. A left homonymous hemianopia was present. Sensation of the left half of the body was diminished to light touch and pain. The blood pressure was 110 systolic, 65 diastolic, and the pulse was 56 per minute. A lumbar puncture revealed a uniformly bloody fluid on two occasions, but the fluid was under no increased pressure. The blood Wassermann reaction was negative and the urine was normal.

Course in the Hospital—The temperature curve subsided to normal in an irregular fashion in ten days. The patient began to improve in a few days after entering the hospital, and a more complete neurologic examination was made on the seventh hospital day. The tendon reflexes on the left had become hyperactive, and there was an ankle clonus. The abdominal and cremasteric reflexes were absent. The extremities showed less weakness but a little rigidity on the left. The left arm was ataxic. The Babinski sign was not present. Examination of the cranial nerves revealed the following observations. The left pupil was larger than the right (Behr's sign in hemianopia). The pupils were round and regular and reacted well to light. Accommodation was weak in the right eye. The optic disks appeared normal. There was no palsy of the extrinsic ocular muscles. The left homonymous hemianopia was unchanged. There was a region surrounding the right eye in the distribution of the first branch of the trigeminal nerve that was hyperesthetic to pin prick and light touch. The supra-nuclear palsy of the left facial musculature was unchanged. There was no alteration of the hemihypesthesia of the left side.

There was a gradual return of strength of the left arm and leg, the arm showing more recovery than the leg. Pain in the right eye persisted for two weeks. At the time the patient was discharged from the hospital one month after admission, the hemianopia and hemihypesthesia were unchanged.

Subsequent Examinations—The neurologic examination was repeated three, six and ten months after the onset of illness. There has been no change in the manifestations for the past four months so that the residual changes may be briefly cited. The hemianopia is complete for all test objects and has been unchanged for six months. The medial side of the left optic disk shows a moderate degree of pallor. The left pupil still is larger than the right but reacts well to light and in accommodation. The left arm and leg show practically normal motor power, although the tendon reflexes are quite brisk and the left cremasteric and abdominal reflexes are still absent. The facial weakness has disappeared. The patient drags the left foot slightly in walking. Plantar flexion on the left is weak and a fleeting Babinski sign is present at times. The left half of the body shows only a slight hypesthesia but this is present to all qualities of sensation especially in the left leg. A disagreeable painful overresponse is obtained by pin prick stimulation of the sole of the left foot.

COMMENT

The spontaneous subarachnoid hemorrhage gave rise to the syndrome that was present shortly after the onset of the illness as well as to the fever and signs of meningeal irritation. The pain in the right eye was probably due to the irritating effect of the blood in the subarachnoid space on the ophthalmic branch of the trigeminal nerve. It is interesting that pain in the right eye followed by headache had occurred seven years previously but had not been followed by other symptoms. This may be interpreted as evidence of leakage from a defect in the vessel wall, which gave rise to the present symptoms. Collier¹⁰ has recently emphasized that subarachnoid hemorrhages occurring in young sub-

10. Collier, James. Cerebral Hemorrhage Due to Causes Other Than Arteriosclerosis. *Brit. M. J.* 2: 519 (Sept. 19) 1931.

jects free from hypertension and other vascular diseases are usually due to the rupture of small "berry" aneurysmal defects in the wall of the small cerebral vessels. These defects are prone to occur where the vessels branch. They ordinarily produce no symptoms unless they adhere to nerves or other structures or unless they clot, calcify or rupture. They have a tendency to rupture slightly, leak slowly and then heal, only to rupture again and give rise to recurrent symptoms. The anatomic studies of Beitzke,¹¹ Marburg,¹² Tuthill¹³ and many others tend to support these views.

The question of the relationship of trauma, which occurred two and one half months before the cerebral insult, is of doubtful significance. Eck¹⁴ is of the opinion that trauma may produce defects in the blood vessel wall which later become solitary aneurysms. He thinks that these rupture and are the basis of late apoplexy after trauma. If the interval between trauma and hemorrhage is more than three months, the traumatic origin of the hemorrhage is unlikely, according to Harbitz.¹⁵

The clinical picture in simple occlusion of the anterior choroidal artery is variable, depending on the site of occlusion. When hemorrhage occurs, as in this case, the analysis is even more complex, because of the factors that pressure, ischemia and edema play in the process. The clinical facts indicate that the maximum damage was done in the region of the lateral geniculate body and the area in which the optic radiations begin. The area of the most posterior portion of the internal capsule was involved in the process to a lesser extent. Although it is conceivable that any of the small tributaries from the posterior cerebral artery or the anterior choroidal artery which penetrate the lateral geniculate body could be the source of the hemorrhage, the most reasonable explanation of the clinical picture would be to assume that a rupture of the anterior choroidal artery itself occurred near the anterior pole of the lateral geniculate body. Here some of the branches that penetrate into the internal capsule would be spared since they branch off farther anteriorly, yet a part of the posterior limb of the internal capsule and the lateral geniculate body would be deprived of blood. The infiltration of blood into the subarachnoid space could produce an irritating effect on the ophthalmic branch of the fifth nerve and thus explain the entire clinical picture.

Another question that arises is whether this symptom picture could be produced by lesions resulting from the occlusion of other cerebral vessels. The studies of Charles Fox⁸ and his school show that hemianopia due to a lesion of the right sylvian artery is accompanied by a monoplegia of the arm or a hemiplegia predominating in the arm. The hemianopia is of a lower quadrant type. A total sylvian artery occlusion is fatal in a short time. On the other hand, a lesion from an occlusion of the posterior cerebral artery produces an upper quadrant hemianopia with an associated thalamic syndrome. A light form of hemiplegia and cerebellar signs may also occur, according to Poppi.⁵ We believe

that this case fits more into the picture of the syndrome of the anterior choroidal artery than into the other syndromes mentioned. In cases in which no anatomic studies are possible, a better descriptive clinical term would be the geniculocapsular syndrome.

SUMMARY

1 The syndrome of the anterior choroidal artery consists of a hemiplegia, hemianesthesia and hemianopia contralateral to the side of the lesion in the central nervous system. The syndrome is very rare.

2 In this case the syndrome followed a spontaneous subarachnoid hemorrhage in a 17 year old boy.

RETROPOSITION OF THE TRANSVERSE COLON

REPORT OF TWO CASES

P. E. TRUESDALE, M.D.

FALL RIVER, MASS.

Abnormal position of the intestinal tract is the result of some disturbance of migration, rotation, descent or fixation during embryonic life. Relatively slight variations in the different stages of development of the intestine result in such developmental anomalies as migratory colon, excessive mobility of the colon, dolichocolon, torsion of the colon or its mesentery or both, common mesentery, and congenital fissure of the mesentery. Important contributions on abnormalities of the colon have been reported by Cruveilhier,¹ Toldt,² Curschmann,³ Morestin,⁴ Tandler,⁵ Koch,⁶ Roud,⁷ de Quervain,⁸ Keene,⁹ Gerlach,¹⁰ McConnell and Hardman,¹¹ Hecker, Grunwald and Kuhlmann,¹² del Campo,¹³ Agrifoglio¹⁴ and Pendergrass.¹⁵ In most of these cases the transverse colon is in normal position but has some defect or torsion of the mesentery. It may be very short or have exaggerated sinuosity. Lack of fixation of the mesentery and torsion from bands or adhesions may result in abnormal positions of the cecum or of the ascending, transverse or descending colon, or it may cause volvulus of a segment of the small or large intestine or both.

Perhaps the rarest of all developmental anomalies of the colon is retroposition of the transverse colon due to inverted rotation of the midgut during the tenth week of embryonic life. In the few cases assembled from the literature the transverse colon dips back into a tunnel behind the duodenum and superior mesenteric artery. Some constriction through torsion of the mesentery or pressure on the transverse colon then causes intestinal obstruction. The cecum and ascending colon become markedly dilated, and in some cases complicated by common mesentery the ileum is also strangulated in

folds of mesentery. In two cases in which death was caused by cancer and tuberculosis, retroposition of the colon was discovered at autopsy.

To understand this congenital anomaly it is necessary to review briefly the early embryologic development of the intestinal tract. In a 5 mm embryo the digestive tract consists of a tube, closed at both ends and attached to the dorsal part of the mesentery, which extends from one end of the embryo to the other. With growth of the embryo, changes in the intestine are marked. By the time the embryo is 9 or 10 mm in length the liver has grown so large that it diminishes the available abdominal space and the intestinal loop is extruded into the root or coelom of the umbilical cord, forming a physiologic umbilical hernia. At this stage, when the embryo is from 5 to 10 weeks old, the first rotation takes place in the gut. While it lies extra-abdominally, the caudal limb lies to the left of the

the upper limb of the U is pushed transversely by the small intestine below and the stomach and liver above. The cecum returns last. As this enterocolic loop reenters the abdominal cavity it undergoes torsion of 270 degrees anticlockwise about the axis of the superior mesenteric artery.¹⁹ The final arrangement of the intestine in the abdomen is seen in figure 1 B, taken from Toldt.²⁰

Eleven cases of retroposition of the transverse colon found in the literature are listed in the accompanying table. The deep position of the transverse colon is due to error of the second-stage rotation of the midgut when the embryo is about 40 mm in length. Lewis²¹ says

In order to produce the anomaly in question, the rotation must have occurred in the reverse direction, that is, with the hands of the clock, so that the large intestine crossed the small intestine on the right side of the body.

Retroposition of Transverse Colon *

Vigi reports that Broman studied retroposition of the transverse colon in a human embryo of three months. He uses Strebl's case by way of illustration however. In his Normale und abnormale Entwicklung des Menschen. Bonn in a thesis on the subject of retroposition of the colon published in Lausanne 1910 reports a case and refers to one found at autopsy by a fellow surgeon Monti.

cephalic limb and the small intestine assumes a position below and to the left of the colon. The colon assumes an inverted-U shape and lies opposite the midline of the posterior abdominal wall¹⁰ (figure 1 A).

The second stage of rotation, which is the important time when the midgut loop is returned to the abdomen, occurs at the tenth week. The return of the intestine to the abdominal cavity is due to a fall of intra-abdominal pressure owing to the increase of space within the abdomen, the extra-abdominal pressure pushes back the contents of the sac.¹⁷ Or, according to Broman,¹⁸ the intestine is gradually sucked back into the abdominal cavity when it has grown sufficiently large. The intestine does not return *en masse*. The proximal limb returns first and occupies the lower part of the abdomen below the liver. Thus the small intestine passes to the left below the colon and mesenteric vessels. The colon retains its inverted-U shape but

The reversed rotation clockwise through an arc of 90 degrees brings about an inverted relationship between duodenum and transverse colon, in such a way that the transverse colon becomes situated behind the superior mesenteric artery and the duodenum lies anterior to it.

Figure 2 A shows the primary loop of a human embryo, 2 B the loop rotated normally anticlockwise, and 2 C the abnormal rotation clockwise, which results later in retroposition of the transverse colon.

This condition is not incompatible with life, but at any time, through some cause, there may be compression of the transverse colon from the duodenum or from the superior mesenteric artery. The rise in tension on the mesentery increases the likelihood of pressure on a segment of the colon, especially in cases in which the complication of common mesentery is present. Other predisposing factors are variation in the length of the segments of the colon, absence of flexure,

abnormally long mesentery, congenital malformation of the mesentery, constricting bands, adhesions, and the like Vig²² believes that cases of retroposition of the transverse colon which are not complicated by a common mesentery do not readily present the possibility of complete intestinal obstruction

Fig 1—A the colon of which the cecum is shown as the lower arm projects forward with the small intestine in the form of an inverted U B the form ultimately taken by the intestine

The report of the following two cases and six others from the literature with illustrations demonstrate the appearance of the viscera and the factors that finally produced acute intestinal obstruction

CASE 1—G L, a married woman aged 45, was admitted to the hospital complaining of severe abdominal colic. She presented a history of intestinal stasis lasting over an indefinite period. There was obstinate constipation, so that she depended almost entirely on enemas for evacuation of the bowel. Two days prior to admission, while traveling she was seized with an attack of colicky abdominal pain, which grew progressively worse. No results were obtained with enemas and the patient was referred to the hospital for operation.

On admission she was suffering from severe abdominal pain. She was nauseated and unable to evacuate the bowel. Her temperature was 98 F, the pulse 74, and respiration rate 22. Symptoms and signs were limited to the abdomen, which was

Fig 2—A primary gastro-intestinal loop of a human embryo B anticlockwise rotation of this loop C abnormal rotation of the intestine clockwise which results in retroposition of the transverse colon

distended, tense and tympanitic. There was generalized tenderness more marked in the right lower quadrant. Peristalsis was audible. Examination of other regions revealed no disturbances.

Though the conditions presented were those indicating an acute surgical condition of the abdomen, in view of the localized tenderness my associates and I thought that we were dealing

with a diseased appendix which had perforated and that the intestinal obstruction was secondary to the inflammatory process.

Under ether anesthesia the abdomen was opened by a right rectus incision. A large viscus was first encountered which proved to be an enormously distended proximal colon. The appendix was normal. The cecum and ascending colon were freely movable but greatly ballooned. The transverse colon was seen to disappear in a tunnel behind the mesentery, and anterior to it were the duodenum and superior mesenteric artery. There was complete obstruction of the transverse colon at its middle and a torsion of the mesentery. From this point the remainder of the colon was completely collapsed (figure 3).

The cecum was needled and suction was applied. By these measures considerable reduction was accomplished. The cecum was then withdrawn extraperitoneally and sutured into the wound but not opened.

In view of the obstruction having its origin in the transverse colon a careful examination was made of the entire lower bowel in search of a neoplasm, but none was found. The gallbladder and ducts were normal and free from adhesions.

Fig 3—Disappearance of the transverse colon as it tunnels the mesentery of the small intestine

The duodenal loop was fully developed. The superior mesenteric artery ran a normal course. The chief points in the picture were an enormously distended cecum, ascending colon, and first portion of the transverse colon to the point of obstruction posteriorly. The remainder of the large intestine was completely collapsed. The torsion of the bowel was corrected and the opening through which the transverse colon passed was enlarged by manual dilation relieving the constriction.

The patient made a good recovery from the operation. The high abdominal distention disappeared, and she took fluids well and complained of only slight abdominal colicky pain. She vomited at rare intervals and the vomitus was not fecal. At first, enemas gave good fecal results and by July 9 normal daily bowel movements were established. July 12, extraperitoneal reduction of the cecum was done and the wound sutured.

There was no recurrence of symptoms or signs of obstruction and the patient left the hospital, July 24, twenty-five days after admission.

CASE 2—E. B. a woman aged 49, single, was admitted to the Truesdale Hospital, March 7, 1915, for the removal of a large tumor of pelvic origin which proved to be an adenocarcinoma of the left ovary. There was secondary invasion of the descending colon involving about 5 inches (12.7 cm) of its

length. The colon was resected from the pelvic brim up to within a few inches of the splenic flexure, leaving a colostomy.

One year later an anastomosis was made between the cecum and the rectum to reestablish the normal outlet of the colon. This was followed by a resection of the ascending and transverse colon. At this operation it was found that the colon passed posteriorly behind the mesentery of the small intestine. It was necessary to pass the left half of the transverse colon through a tunnel posteriorly in order to remove it.

Thus we observed incidentally a retrodisplaced transverse colon that had caused no symptoms.

Figure 4 shows different illustrations of retroposition of the transverse colon selected from case reports.

Fig. 4—A Black's case. Enormously dilated cecum and obstruction at midtransverse colon from a twist in a direction that looked as though the cecum had turned forward from right to left through an arc of 180 degrees. The ileum passed behind the cecum and entered on the right. The duodenum passed in front of the transverse colon.

B Bastiaen's case. At operation loops of small intestine were found distended and constricted by the edges of a fissure of the mesocolon and by the transverse colon. The mesentery of the transverse colon was abnormally short and lay very close to the vertebral column.

C Tscherning's case. The condition was discovered at autopsy. A distended cecum was found between the umbilicus and the symphysis. The contents of the cecum could not be forced into the ascending colon until the small intestine was removed from the abdominal cavity. Then the cecum went back to its normal position in the right iliac fossa. The duodenum was adherent to the posterior abdominal wall. The colon was in retroposition and the cecum and ascending colon were freely movable to the right of the mesentery. There was a common mesentery of ileum and ascending colon. The root of the mesentery was adherent to the posterior abdominal wall as well as below the colon so that the colon bored through the base of the mesentery. No special transverse colon could be made out. There was, however, a transverse bend of the ascending colon at the point at which it passed through the mesentery.

D Strehl's case. When laparotomy was done congested discolored coils of small intestine gushed out. The transverse colon without developing a hepatic flexure had passed under a bridge of mesentery of the ileum in front of the spine and had become strangulated. The transverse colon was retrogastric and its sinuous course could not be changed by traction. The mesentery was attached to the spine just beneath the opening through which the colon passed. The colon had no hepatic flexure.

E Hausmann's case. At operation the cecum was found high and greatly distended. The ascending colon and ileum had a common mesentery. The transverse colon lay very deep behind the duodenum without a free mesentery and was bound down to the posterior abdominal wall. It was impossible to put back the cecum and ascending colon in their normal positions or to move the transverse colon from its retroposition.

F Vigli's case. At autopsy loops of badly discolored ileum were found strangulated by mesentery. The ascending colon dipped back into a tunnel and was extraperitoneal, bound down by a pericolic veil. To trace the course of the ascending and transverse colon it was necessary to incise this membrane and pass by the duodenum and superior mesenteric artery. The transverse colon passed through the mesentery, reappeared at the left of the median line and forming the splenic flexure finally continued its normal course to join the sigmoid.

These cases of retroposition of the transverse colon are to be differentiated from cases of torsion on the peduncle of mesentery with ensuing volvulus of a segment of large intestine or, in rare instances of the entire small intestine as well. Volvulus occurs after development is complete, as a result of torsion of the mesentery. The intestine can be restored to its normal position through detorsion anticlockwise as in Kallio's²³

two cases and in Caporale's²⁴ case of so-called chronic torsion of the transverse colon. In the latter, rotation of the stomach was also present. Several cases of volvulus result in a position of colon and small intestine almost identical with those of true retroposition, as in Boyd's²⁵ case. The explanation given is that a loop of small intestine got behind the free ascending and transverse colon from below, rose through the dorsal mesogastrium behind the stomach and pulled after it all the rest of the small intestine and free part of the colon. This produced an intertwining of the stomach and intestine and volvulus of the small intestine and free part of the colon, so that the transverse colon came to lie dorsally from the root of the mesentery and the duodenum.

Some cases are hard to diagnose. Hausmann's⁶ case is still in doubt, possibly because his explanation of the retroposition of the transverse colon is that the umbilical loop first underwent torsion anticlockwise, but the ascending limb as it grew turned behind the duodenum. Ekehorn²⁷ and Strehl²⁸ say, therefore, that only through a volvulus could the limb change its course. Black²⁹ however, classifies it as a case of true retroposition, which is probably the correct interpretation.

It is apparent from end results in the table that, when acute intestinal obstruction occurs, surgical intervention is imperative. The patient's condition, however, contraindicates radical measures, such as an anastomosis or resection until the patient has recovered from the acute obstruction. Preliminary cecostomy can be done with less risk and after normal evacuation of the bowels has been established further surgical measures may be undertaken to relieve constriction and correct torsion of the bowel or mesentery. In all cases treated by radical operation the prognosis is discouraging.

So-Called New Diseases—We have no reliable evidence of the existence of infantile paralysis in epidemic form before 1840, and it seems likely that if a disease of such striking characteristics had existed in epidemic form it would have found its way into the seventeenth and eighteenth century literature. In regard to encephalitis (*culpo dictu*, sleeping sickness), it is equally difficult to find reliable evidence of its existence before the eighteenth century. In 1712 Bierner studied an epidemic in Tübingen which was popularly known as sleeping sickness, because it was accompanied by somnolence and brain symptoms. The 'coma somnolentum' observed by le Pecque de la Cloture in 1769 was similar and, like the disease of 1917, was associated with influenza. Ozanam mentions a condition of like nature occurring in Germany in the last decade of the eighteenth century, in Lyons in 1800 and in Milan in 1802. After this time no reliable evidence of any disease of this kind can be found until 1917. In that year, synchronous with the first considerable outbreak of influenza, a group of encephalitis cases occurred in Vienna. Soon after that others appeared in France, Great Britain and Algeria, then during the latter half of 1918 cases were seen in North America, and by May 1919 had been reported from twenty states—the largest number from Illinois, New York, Louisiana and Tennessee. To all intents and purposes, this was a new disease to our generation, and up to the present time the virus of this form (lethargic encephalitis) has never been successfully transferred to animals—Zinsser, Hans. Rats, Lice and History, Boston Little Brown & Co. 1935.

THE EFFECT OF CEVITAMIC ACID
INJECTIONS ON CAPILLARY
RESISTANCE

GILBERT DALLDORF, M.D.

AND

HOLLIS RUSSELL, M.D.

VALHALLA, N. Y.

Relative fragility of skin capillaries is a common condition¹. It may be found in individuals of all ages who are otherwise free of signs or symptoms of scurvy. Nevertheless, increase in the antiscorbutic value of the diet of such individuals increases their capillary resistance. This borderline nutritional disorder has been called subclinical scurvy, and a general experience with experimental nutritional diseases suggests that other slight deviations from health are probably present in such persons. The condition is therefore deserving of study. The influence of cevitic acid on this condition forms the basis of the present report.

METHOD

The cevitic acid used was Cebione Merck & Co. The product was assayed against a standard iodine solution by Harris's method² and found to be pure within the limits of error of the method. The acid was

Chart 1—Effect of two injections of cevitic acid on the capillary resistance of a young woman during a period of twelve days

administered intravenously, 100 mg being dissolved in at least 10 cc of distilled water and injected slowly. No reactions have occurred. Since the acid deteriorates rapidly once the ampule is opened, the injections were made as soon as the solution was prepared.

The capillary resistance was measured with our own resistometer. The instrument has recently been improved through an automatic valve and the use of a smaller pump. The cup size was identical with that previously used. The outer surface of the arm was tested, and the cup was applied for one minute. Capillary resistance is expressed as the least negative pressure required to produce macroscopic petechiae.

RESULTS

Fourteen residents of the local county home who were found to have reduced capillary resistance were first tested. In all but three cases, 100 mg of cevitic acid was injected. In the three exceptions, 50 mg was used. These persons were all up and about, but many were old and feeble. All of them showed a marked and prompt response in capillary resistance which persisted for at least twenty-four hours.

From the laboratories of Crosslands Hospital
1 Dalldorf, Gilbert. A Sensitive Test for Subclinical Scurvy. 10 Man. Am. J. Dis. Child. 40:794-802 (Oct.) 1933.
2 Birch, T. W. Harris, L. J. and Ray, S. N. A Microchemical Method for the Determination of Hexuronic Acid in Foodstuffs. Biochem. J. 27:590 (No. 2) 1933.

Of ten other county home residents, four were found to have fragile capillaries, and these likewise responded promptly to cevitic acid. In this group the average capillary resistance before injection was 24 cm of mercury negative pressure. After injection the average rose to 35 cm. The former value we have come to associate with groups on diets poor in fresh fruits and vegetables, the latter value is the normal for well fed groups.

REPORT OF CASES

In order to illustrate more clearly the influence of cevitic acid on capillary resistance, the following cases are reported in greater detail.

G. T., a woman, aged 19, sent into the hospital from the hematologic clinic had hypochromic anemia, and her history

Chart 2—Effect of a single injection of cevitic acid on the capillary resistance of a boy during a period of seven hours. The concentration of cevitic acid in the urine on four occasions also is shown.

showed that her diet had been limited in fruits and vegetables. Her capillary resistance was 15 cm of mercury on each of several days. She was given 100 mg of cevitic acid intravenously. Forty-five minutes later the resistance was 20 cm of mercury. Four hours after the injection it was 30 cm of mercury. Chart 1 shows the effect of this and a subsequent injection of the acid over a period of eleven days.

Patients 2 and 3 were boys, aged 8 and 10 years, who were residents of the orthopedic pavilion. One was being treated for congenitally dislocated hips and the other for postpoliomyelitis paralysis. One had been in the hospital for two months and the other for four months. Their diets had contained ample amounts of antiscorbutic foods, since the average capillary resistance for the entire ward was nearly 35 cm of mercury.

Chart 3—Effect of a single injection of cevitic acid on the capillary resistance of a boy during a period of seven hours. The concentration of cevitic acid in the urine on four occasions also is shown.

Each had had 4 ounces (120 cc) of fruit juices a day for the entire period of his stay in the hospital, in addition to the usual diet. Both had eaten well. Neither had any disorder other than the defects they were being treated for.

Both boys nevertheless, showed many petechiae at 15 cm of mercury partial vacuum. Each was given 100 mg of the acid. Each responded promptly within an hour. The entire records are given in charts 2 and 3. The urine output of cevitic acid is likewise shown. The total output of acid was 85 and 74 mg respectively within seven hours. As the charts show the increased output was the result of increased concentration of the acid. The urine volume was not conspicuously affected.

The boys were tested on two occasions. The cevitic acid output during the second test was 58 and 39 mg of cevitic acid during a five hour period.

COMMENT

It is evident from these results that cevitamic acid promptly increases the resistance of the skin capillaries to rupture. The prolonged effect of the injections shows the action to be a specific one of the cevitamic acid and not an immediate reaction to acid as such.

The last two cases suggest that individual requirements of antiscorbutic foods vary or that absorption or utilization may be affected. Since the acid is readily oxidized, it may be that these two boys destroyed cevitamic acid in their stomachs before it was absorbed. This matter requires further examination.

The results we have secured are identical with those reported by one of us four years ago as occurring in scorbutic guinea-pigs following the injection of neutralized orange juice³; they are similar to but more rapid than the effect in both guinea-pigs and children of feeding large amounts of antiscorbutic foodstuffs.

The results further substantiate our observation that the common condition of capillary fragility represents a mild form of scurvy, a "subclinical scorbutus."

CONCLUSIONS

The parenteral injection of cevitamic acid has a prompt and prolonged effect on the capillary resistance of individuals whose capillaries are fragile owing to dietary inadequacy or faulty absorption of cevitamic acid.

Clinical Notes, Suggestions and New Instruments

A SPLINTER OF WOOD LODGED IN THE URINARY BLADDER

JAY J. CRANE, M.D., AND E. E. MOODY, M.D., LOS ANGELES

R. B., a boy, aged 7½ years, while playing, July 1, 1934, fell from a garage roof, lighting astride a picket fence. Examination revealed a laceration 1 cm. long on the inner aspect of

Fig. 1—The point at which the splinter of wood pierced the inner aspect of the thigh.

the upper third of the left thigh, through which a probe was passed, but no foreign body was found. During the first four days the only symptom complained of was a dull ache over the bladder area, which gradually disappeared. A few red

blood cells were found in the urine immediately after the accident and continued to be present during this period. By the end of the second week pus was found in the urine, accompanied by a tickling sensation in the urethra during the act of micturition. The laceration now was entirely healed, and it was thought safe to allow the patient to go to a boys' camp, where he could be under observation. Here he engaged in the usual camp activities. Frequent urinalyses during a period of four weeks showed pus cells and an occasional red blood cell to be constantly present but unaccompanied by subjective symptoms.

Fig. 2—Splinters of wood after removal from bladder. A the smaller piece passed spontaneously through the urethra to the external meatus, where it was extracted. B the larger piece was removed from the bladder through a cystoscope.

July 30 he was returned from the boys' camp because of difficulty and pain on urinating, in conjunction with a swelling of the penis, which appeared very suddenly the same morning.

Examination on the latter date revealed the penis to be swollen and discolored as the result of the evident local disturbance of blood supply caused by the swelling. The picture as a whole was not unlike a perimeatal abscess. Urine was voided with difficulty but there was little discomfort except on voiding. Because the patient would not permit us to palpate the penis, a general anesthetic was given, at which time a piece of wood 3.5 cm. by 0.5 cm. was readily palpated, lodged in the pendulous urethra. By manipulation the splinter was removed, followed by the ability to urinate freely. Roentgenograms revealed a second and larger piece of wood 6 cm. by 0.5 cm. to be resting crosswise in the pelvis. Several smaller splinters were visualized in the soft tissues in the leg. The fragments of wood cast only the faintest shadow in the roent-

Fig. 3—Reconstructed pieces of wood showing their relationship as they passed into the bladder.

genogram. Since the patient was symptom free, six days was allowed to elapse before a cystoscopic examination was made, at which time the larger fragment was visualized lying free in the bladder (one end was pointed and the other end blunt) in the bladder (one end was pointed and the other end blunt). A reddened area on the left lateral wall of the bladder indicated the point of entrance of the wood. Through an 18 French panendoscopic sheath, which passed readily, the sharp point was grasped with a pair of foreign body extractors and pulled into the sheath. By retaining a firm grasp on the splinter the sheath was removed, followed by the splinter. Recovery was uneventful.

3 Dalldorf, Gilbert. A Criterion of Hemorrhagic Diathesis in Experimental Scurvy. *J. Exper. Med.* 63: 289-297 (Feb.) 1931.

During the next three months several smaller pin-sized fragments were passed. November 14, a cystoscopic examination revealed a normal bladder and no evidence of remaining pieces. The reddened area on the left lateral wall of the bladder was entirely healed.

It is apparent that the splinter of wood was driven up the inner aspect of the left thigh through the obturator foramen and into the bladder, where the fragment split and the shorter piece attempted to pass spontaneously, being caught by the normally constricted external urethral orifice. No evidence of urinary extravasation or hemorrhage occurred at any time.

THE MANAGEMENT OF PREECLAMPTIC TOXEMIA AND ECLAMPSIA

A REPORT OF THE AMERICAN COMMITTEE ON
MATERNAL WELFARE

Eclampsia, and the forms of toxemia associated with it, cause, annually, about 30 per cent of the approximately 15,000 maternal deaths in this country. There are many of the women who survive the convulsions and acute stages, or who recover from severe, non-convulsive forms of toxemia and have permanent vascular or renal injuries which impair their health and shorten their lives.

The American Committee on Maternal Welfare¹ is intensely interested in being of any possible assistance in lessening this morbidity and mortality and to this end has prepared this brief article on the treatment of the nonconvulsive forms of toxemia of pregnancy (preeclampsia) and of the convulsive types (eclampsia).

The question of the exact terminology of these forms of toxemia is not of great moment. The term "preeclamptic toxemia" is used in the title chiefly because it is probably familiar to more physicians than any other term used to define toxemia of late pregnancy, and because it conveys the idea that the toxemia may proceed from the nonconvulsive or preeclamptic stage into the stage of convulsion or eclampsia. There will be no discussion in this article of the etiology of these forms of hypertensive toxemia, nor is it intended to describe the pathologic aspects of the disease. Rather, this statement is concerned with practical measures which are of proved value in prophylaxis and treatment.

It is well to state at the beginning that the toxemia of late pregnancy is a nonsurgical condition which should be treated by medical measures in the vast majority of cases. Careful investigation of the causes of maternal deaths throughout this country has shown that the maternal death rate is more than 20 per cent in many localities following cesarean section or other operative measures for eclampsia. Maternal mortality is reported to be about 5 per cent in series of cases in which treatment is primarily by medical measures. This is particularly true if medical treatment is carried out consistently before measures are used to terminate pregnancy.

PERMANENT INJURIES OR DEATHS ATTRIBUTED TO
THE NONCONVULSIVE AND CONVULSIVE FORMS
OF TOXEMIA OF LATE PREGNANCY ARE
LARGELY PREVENTABLE

In large measure, the cardiorenal and vascular injuries and deaths attributed to severe, nonconvulsive toxemia and to its convulsive culmination, eclampsia, constitute preventable diseases. Prevention rests on careful observation and management of pregnancy, to which the term "antepartum care" has been applied. The incidence of nonconvulsive or preeclamptic toxemia is apparently lowered by means of systematic application of some of the simple principles of prenatal care, which will be described later, and most cases of toxemia are discovered before the appearance of alarming symptoms, which may progress to eclampsia and convulsions.

A number of observers have reported series of cases in which adequate antepartum care has been given and in which the occurrence of eclampsia is appreciably less than it is in series composed of like numbers of pregnant women who lacked such care.

EARLY SIGNS OF PREECLAMPTIC TOXEMIA

Three instruments available to any physician who is caring for any pregnant woman are the apparatus for determining blood pressure, scales for weighing the patient, and the test tube, which is used as a routine for detecting and estimating roughly the amount of albumin in the urine. There is almost invariably a slight but distinct rise in both systolic and diastolic blood pressures several weeks before any appreciable amount of albumin can be detected in the urine of a woman who has incipient, nonconvulsive toxemia. It has also been shown that women who do not gain, during pregnancy, more than 20 to 25 pounds (9 to 11 Kg) over and above their normal weight are rarely subject to the development of severe toxemia. These statements rest on proved evidence.

ESSENTIAL MEASURES FOR THE DETECTION AND MANAGEMENT OF TOXEMIA OF LATE PREGNANCY

At the first prenatal visit the reasons for proper elimination and diet are explained to the patient. She is instructed to eat a general diet, including a requisite amount of foods containing protein and the vitamins, and a reduced amount of the weight-producing foods, fats and carbohydrates, to drink at least 3 pints of water daily and to use salt sparingly. Some physicians urge removal of foci of infection as a prophylactic measure. Every two to four weeks, if possible, from the third month of gestation to the seventh, and from then on at least every two weeks, the pregnant woman visits the office of her physician. At each visit a record is made of her blood pressure, weight and results of urinalysis. If the woman's blood pressure has risen from her usual normal of about 120 mm of mercury systolic and 80 diastolic, or less to 135 systolic and 90 diastolic or more, the physician has suggestive evidence of incipient toxemia, and this evidence is not to be ignored. If a continued rise in blood pressure is verified by further readings, the physical activities and diet of the patient are limited, free bowel movements are induced by saline cathartics, and sedatives may be used particularly if the patient is tense, apprehensive or not sleeping well. Bromides, 15 grains (1 Gm) or phenobarbital one-half to three-fourths grain (0.032 to 0.05 Gm), three times a day, or other mild sedatives, lessen the nervous tension of the patient and tend to lessen arterial spasm.

¹ The members of the committee are: Drs. Fred L. Adair, Chicago chairman; George W. Kosmak, New York, vice chairman; James R. McCord, Atlanta, Ga., secretary; Frederick H. Falls, Chicago, treasurer; LeRoy A. Calkins, Kansas City, Mo.; Robert L. DeNormandie, Boston; Rudolph W. Holmes, Chicago; Robert D. Mussey, Rochester, Minn.; Everett D. Plass, Iowa City; Arthur J. Skeel, Cleveland; and Philip F. Williams, Philadelphia.

TREATMENT OF TOXEMIA OF PREGNANCY

In spite of this management there may be a further rise in blood pressure often accompanied by undue gain in weight, which usually is attributable to retention of tissue fluids due to disturbed water balance, albumin is usually found in the urine, which is scanty and of high specific gravity. The woman should be put to bed with such evidences of increasing toxemia and should receive a reduced diet particularly a reduced amount of meat protein and a minimal amount of salt, while edema is present the total intake of fluid may be limited in amount to correspond with the total amount of urine excreted in twenty-four hours. If preferred the patient may be given a diet of milk and fruit juice. The procedures outlined in the foregoing will control most of the cases of mild toxemia. The problem is more difficult in the cases in which the condition is not so controlled and in those in which the patients present themselves to the physician in a more advanced stage of toxemia. As a general rule it may be said that a blood pressure of 170 systolic and 105 diastolic, or more, presents a more immediate hazard. Alarming symptoms may arise when the blood pressure is considerably lower than this.

After an adequate trial of various measures to insure sedation, rest, restricted diet and elimination and perhaps intravenous administration of solutions of magnesium sulphate or of dextrose or both, following the technique to be described later, persistence or increase of high blood pressure with accompanying symptoms of toxemia, confront the physician with the necessity of considering the termination of pregnancy.

It is generally considered that toxemia of the later months of pregnancy may proceed from mild to severe stages and finally to a climax of eclampsia with convulsions. In all cases of mild toxemia treatment should be efficient for in any case the condition may become severe. As the disease progresses in severity and duration the risk to both mother and fetus is increased. Long-continued toxemia is more productive of chronic arterial or renal injury than is a shorter, possibly more severe toxemic state. Fortunately in few cases of acute toxemia does the condition become severe prior to the period of viability of the fetus at twenty-eight weeks. However, in the interest of the mother, pregnancy should be terminated if and when it is found that the toxemia cannot be controlled.

METHODS OF INDUCTION OF LABOR

Various measures have been advised for induction of labor. If the need for induction is not immediately urgent, administration of castor oil and quinine sulphate (not more than a total dosage of 20 grains, or 1.3 Gm.) may be tried. Physicians who have had experience with pituitary preparations sometimes use five or six doses of 1 to 2 minims (0.07 to 0.13 cc.) of the extract of the posterior lobe or of its oxytocic fraction, repeated at intervals of half an hour, to induce labor. This medication is given subcutaneously and is discontinued as soon as labor begins, its use, however, is hazardous.

Mechanical Induction—If the need is more immediate it is probable that the simplest and safest method is to rupture the amniotic sac. This procedure may be inadvisable because of certain conditions. One of these conditions is fetal and pelvic disproportions, another is the presence of a long, thick, uneffaced uterine cervix, which is likely to cause failed induction or dystocia. The patient's vulvar hair is clipped or shaved, the vulva

and perineum are properly cleansed and prepared, and the physician scrubs and gloves his hands as for any intra-uterine manipulation. Some antiseptic solution, such as 1 to 2 fluidounces (30 to 60 cc.) of 1,000 aqueous solution of mercurochrome, metaphen or merthiolate may be instilled into the vagina. The membranes are ruptured by means of a sterilized orange stick or other appropriate instrument. Labor is induced by loss of amniotic fluid rather than by rupture of the sac, and in some instances the fetal head or breech must be pushed up just enough to allow the major portion of the fluid to leak out of the uterus. If labor does not begin within twelve hours after this, 1 ounce (30 cc.) of one of the named antiseptic solutions may be instilled into the vagina every four hours. In cases of the sort under consideration, morphine, chloral, derivatives of barbituric acid or other sedatives are of value in lessening irritability of the nervous system before, during and after labor.

ECLAMPTIC CONVULSIONS

For many years it was the prevailing custom to deliver as soon as possible if the woman had eclamptic convulsions. Turning from the rapid, forcible dilation of the cervix and immediate delivery formerly employed which was followed by a maternal mortality of between 20 and 30 per cent, some physicians in more recent years have resorted to immediate cesarean section, which in many localities has a maternal mortality almost as high. Again too much emphasis cannot be put on the importance of treating the disease first and the pregnancy later. After the convulsive manifestation of the disease has been controlled, termination of pregnancy and method of delivery can be considered from the obstetric standpoint.

TREATMENT OF ECLAMPSIA

As soon as possible after the onset of convulsions, the patient should be given morphine hypodermically. An initial dose of from one-fourth to one half gram (0.016 to 0.032 Gm.) is used, depending on the severity of the attack and the respiratory rate. Some physicians assert that administration of morphine, in repeated doses constitutes an excellent method of treatment of eclamptic convulsions, whether the morphine is used alone or in conjunction with other therapy not aimed at sedation. After the initial dose, this procedure calls for repeated injections of morphine from one-fourth to one-sixth grain (0.016 to 0.01 Gm.) every half hour, until the rate of respiration is reduced to 12 or 14 per minute. Subsequent doses should be given whenever the respirations rise to more than 16 per minute. There is wide variation in the respiratory response to morphine yet that response is the best available index of sufficient dosage, and if this method of treatment is decided on the drug must be administered until the desired effect is obtained. The dose should be graduated according to the size of the patient, the severity of the seizures and its effect.

Many physicians who practice obstetrics are administering successfully 20 cc. of 10 per cent solution of magnesium sulphate intravenously, or a similar amount of 25 per cent solution of magnesium sulphate intramuscularly, every hour until the convulsions have been controlled. Solution of magnesium sulphate may cause sloughing of subcutaneous or fatty tissue, and care must be taken to place the solution in the vein or well into the muscle, as the case may be. Magnesium sulphate is said to act in four ways: first as a depressant

of irritability of nerve cells, second, by drawing fluid from the edematous or wet brain, thereby lessening the coma, third, by drawing fluid from the body tissues and increasing the urinary output, and, fourth, by reducing the respiratory exchange. If control of convulsions is not obtained soon, sedatives such as sodium amylal, from 6 to 12 grains (0.4 to 0.77 Gm.), or pentobarbital sodium, from 6 to 9 grains (0.4 to 0.6 Gm.), may be given intravenously.

When the convulsions are under control, or sooner if desired solution of dextrose is given intravenously. The beneficial effects of hypertonic solution of dextrose in cases of toxemia are as follows: It replenishes depleted glycogen, combats acidosis, aids in withdrawal of fluids from the edematous brain and body tissues, dilutes these fluids, and promotes diuresis. For this purpose 250 cc. of 25 per cent solution is given, or 1,000 cc. of 10 per cent solution, if the patient is in need of fluids. In giving solution of dextrose the physician must observe several precautions: 1. The dextrose should be obtained in ampules or in specially prepared liter flasks of proper dilution, from a reliable pharmaceutical house. 2. If ampules are used, the water in which the dextrose is diluted should be freshly distilled or double distilled. 3. New rubber tubing should never be used unless it has been boiled in an alkaline solution. 4. The solution of dextrose should be given warm (100 F.) and slowly. The solution of dextrose may be given every eight hours until labor is over and often is of value after delivery.

Because the interval between convulsions may be short, or sometimes prolonged, it may be difficult to determine when the disease is under control. An indication that the eclampsia is under control is cessation of convulsions and returning consciousness, together with the appearance of perspiration and establishment of diuresis and catharsis. The degree of unconsciousness and coma is probably a better prognostic sign than the convulsive attacks. The patient whose periods of unconsciousness are prolonged and gradually become deeper offers a more serious prognosis than one with more convulsive attacks but milder degrees of unconsciousness.

After the control of convulsions it is necessary to decide how pregnancy should be conducted in the best interest of mother and fetus. When gestation has reached the period of viability it is safer for both of them if the pregnancy is terminated. When the period of viability has not been reached, the chance of the fetus surviving is exceedingly remote and the life of the mother is endangered by continuation of the pregnancy. The course of the physician is clear. When the convulsions have been checked, termination of pregnancy should be advised by the method best suited to the obstetric indications and environment. If the patient or her relatives insist on deferring termination of pregnancy, measures previously described may be continued as indicated, until the period of viability.

Depending on the condition of the patient, induction of labor by medical measures may be attempted, although usually to avoid delay it is better to induce labor by rupturing the membranes and draining the amniotic fluid. The question of cesarean section is decided by the obstetric indications in each case rather than by the presence of toxemia and convulsions. Toxemia in itself is not an indication for cesarean section. During labor the use of sedatives is advisable and magnesium sulphate or solution of dextrose is used when indications arise.

POSTPARTUM CONVULSIONS

The possible occurrence of convulsions does not end with termination of pregnancy. The physician should remain with a toxemic patient for at least an hour after delivery of the infant, whether or not the mother has had convulsions. The use of sedatives and other measures to combat the toxemia may be indicated by restlessness of the patient, persistently high blood pressure, edema or other symptoms.

COMMENT

In the foregoing description of the management of preeclamptic or nonconvulsive toxemia, and in the description of the management of convulsive toxemia, eclampsia, no attempt has been made to include all available methods of examination and treatment but rather to give a brief outline of conservative, comparatively simple, and reasonably effective measures available to the general practitioner as well as to the specialist in obstetrics. Severe preeclamptic toxemia or eclampsia constitutes a hazard in the management of which consultation is highly desirable and adequate hospital facilities are distinctly advantageous.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
HOWARD A. CARTER, Secretary

AN APPRECIATION

The Council on Physical Therapy wishes to take this opportunity to express its appreciation for the valuable advice and assistance of the following consultants, who have so generously offered their services in the investigation of apparatus and in the consideration of other problems which have confronted the Council: Drs. Fred L. Adair, Francis Heed Adler, Howard Ballenger, M. Herbert Barker, William Bierman, Walter M. Boothby, Curtis Burnam, Fremont Chandler, Elton R. Clark, Virgil Counsellor, Alfred Cowan, Arthur Curtis, L. F. Curtiss, Irving S. Cutter, Geza de Takats, Cecil K. Drinker, F. H. Ewerhardt, Samuel Feinberg, Jonas Friedenwald, Sanford Gifford, Samuel Gordon, Leon A. Greenberg, George P. Gubor, Allan Hemingway, John Severy Hibben, J. Burton Hoag, Myrta M. Knowles, Disraeli Kobak, A. J. Kotkis, Richard Kovacs, Herman L. Kretschmer, Eugene Landis, Henry Laurens, Philip Lewin, Franklin P. Lowry, John MacNie, Charles O. Molander, Bernard Mortimer, Tell Nelson, Clarence A. Neymann, Earle Phelps, George E. Pfahler, Lewis J. Pollock, Leander Riba, George E. Shambaugh, Alfred E. Shaw, Clifford B. Walker, Grant E. Ward and John G. Wilson.

ADLANCO ULTRATHERM ACCEPTABLE (Short Wave Diathermy)

Manufacturer: Adlanco X-Ray Corporation, 54 Lafayette Street, New York

The Ultratherm is a short wave diathermy machine employing vacuum tubes for generating high frequency alternating currents. The circuit is of a well known type recognized as delivering good output at approximately 6 meter wavelength for the given cost of manufacture. Raw alternating current is impressed on the plates of the vacuum tubes, hence only one half of the wave, the positive part, of the 60 cycle alternating current is used in the generation of high frequency currents (fig. 1).

The internal construction of the machine, that is the transformers, condensers and circuit, appear satisfactory, following the best engineering practice. All parts are rigidly constructed which is an important factor in the production of high frequency

electrical currents. In a test conducted for the Council, the transformer was declared satisfactory and the temperature rise kept within the limits of safety.

The internal temperature within the cabinet itself reaches, after several hours of operation 76 C. Since the cabinet is made of metal and well insulated, this high temperature will not cause any serious damage. The shipping weight is 250 pounds.

The patient is at no time directly connected with the generating circuit that is with the 60 cycle alternating current. The use of "indirect" coupling is desirable as it eliminates the possibility of the patient receiving any low voltage electrical shocks (fig 2).

The register on the side of the machine recording the number of hours of service on the vacuum tubes is meritorious.

In a Council test the wavelength of a stock machine was found to be between 56 and 6 meters, according to the conditions under which the machine was operating. These measurements were made on both the wave meter and Lecher wires.

Physical tests for power input were made on the Ultratherm with a Weston wattmeter. On an average of five tests with the Adlanco Ultratherm operating at full load, the power input was 1514 watts. So far as it is known, there is no standard or acceptable method of determining the power output of a short wave diathermy machine.

Fig. 1—Adlanco Ultratherm

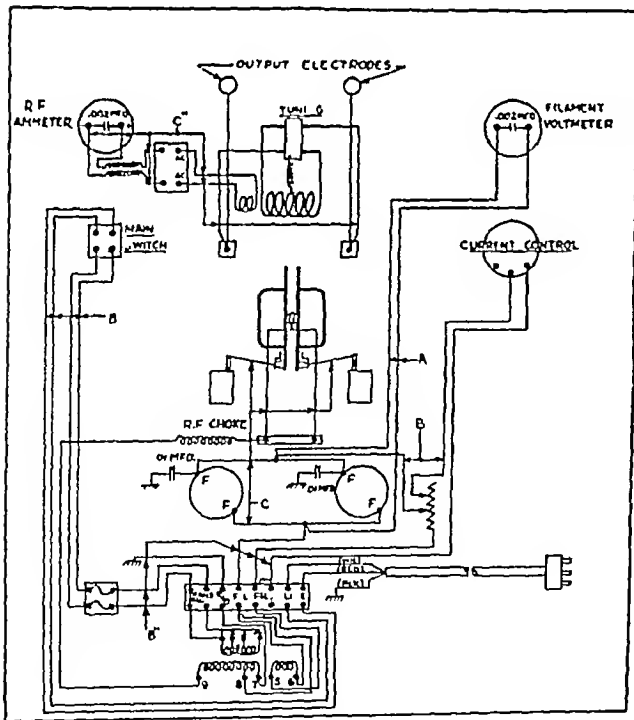

Fig. 2—Circuit of Adlanco Ultratherm

The high frequency meter on the panel of the Ultratherm does not indicate the amount of current flowing through the patient but it does indicate when the patient's circuit is in resonance. The patient's tolerance, therefore, is the controlling factor for the energy applied during treatment. One other meter on the machine records the voltage across the filaments of the tubes.

A stock Ultratherm was placed in a clinic acceptable to the Council on Physical Therapy and was used in the treatment

of many conditions in which diathermy is indicated. The machine appeared to give satisfactory service. The heating effects of the Ultratherm were investigated in a series of observations on anesthetized dogs. An average of twelve observations show that there was a substantial rise in temperature in the kidney, rectum, liver and spleen. In this series of tests the unit operated at full load.

The tissue heating effect in the human thigh was also investigated. The thermocouples were introduced into the subcutaneous and deep-lying tissues (quadriceps extensor) and after twenty minutes' treatment on eight subjects and the machine operating at the patient's tolerance a substantial rise in temperature was observed in the subcutaneous and muscle tissues. The evidence indicates that the temperature gradient is from the outside to the inside. In other words the temperature is higher nearer the surface of the skin than at any point below the surface.

The clinical indications for the Ultratherm are comparable to those of the conventional diathermy. Claims such as specific physiologic action, specific bactericidal action for certain wavelengths, and even heating through the tissues, were not substantiated in the Council's investigation. The machine is not recommended by the manufacturer for surgical diathermy or for hyperpyrexia treatments. Burns are possible, but the likelihood of their occurring with the Ultratherm is not as great as with the conventional diathermy.

In view of the favorable report on this machine, the Council on Physical Therapy voted to include the unit in its list of accepted devices for physical therapy.

INDUCTOTHERM ACCEPTABLE (Short Wave Diathermy)

Manufacturer: General Electric X-Ray Corporation, Chicago.

The Inductotherm is a recent addition to the diagnostic and therapeutic line of the General Electric X-Ray Corporation. The purpose of this unit is to administer therapeutic heat to the body tissues thus producing a heating effect comparable to that of diathermy. Conventional electrodes are not used, and no metal to skin contact is made with the patient. High frequency electrical energy is applied through a flexible heavily insulated cable, which is wound around or about the part to be treated. The exact physical phenomenon taking place within the tissues causing the heat to be generated has not been fully explained. It is believed, however, that within the helical coil through which the high frequency current from the device flows, there is set up an alternating magnetic flux, having the same frequency as the current in the coil. If a conductive material is placed within the coil, an electromotive force will be induced in it. As a result of this induced voltage, eddy currents of the same frequency as the exciting current will flow in the conductive material. If living tissue is subjected to the magnetic field within the coil of the Inductotherm, heat will be produced in such tissue, but there will be no neuromuscular response to the eddy currents induced in the tissue because the frequency of these currents is very high, 12,000,000 cycles per second far above the frequencies that elicit muscular contraction.

Fig. 1—Inductotherm

The circuit used in the Inductotherm is of the Hartley push-pull type, employing power vacuum tubes. The patient circuit is connected inductively to the oscillating or tank circuit. One stock unit was investigated in a laboratory acceptable to the Council. The electrical insulation was considered satisfactory.

Dissolve 0.01 Gm. of ephedrine hemihydrate in 1 cc. of water and add 0.1 cc. of copper sulphate solution (10 per cent) followed by 1 cc. of sodium hydroxide solution (20 per cent) a reddish purple color develops. To this solution add 1 cc. of ether shake the mixture and compare with a tube made up similarly, but without using ether the reddish purple is partially extracted (apparently decolorized by the ether).

Dissolve 0.05 Gm of ephedrine hemihydrate in 10 cc of chloroform and allow the solution to stand 18 hours, evaporate the chloroform spontaneously, white crystals of ephedrine hydrochloride appear wash with 2 cc of chloroform dry spontaneously the crystals melt at 214-220 C.

Dissolve 0.05 Gm of ephedrine hemihydrate in from 30 to 40 cc of distilled water add 1 cc of diluted nitric acid and 1 cc of silver nitrate solution less turbidity results than in a control tube containing the same quantity of reagents to which has been added 0.1 cc of fiftieth normal hydrochloric acid (limit of chloride). Dissolve 0.1 Gm of ephedrine hemihydrate in from 30 to 40 cc of distilled water add 1 cc of diluted hydrochloric acid and 1 cc of barium chloride solution no turbidity develops in 10 minutes (limit of sulphate).

Transfer about 1 Gm of ephedrine hemihydrate accurately weighed to a 10 cc graduated flask and dissolve by adding 7 cc of water and 1 cc of hydrochloric acid dilute the solution to 10 cc transfer the solution to a polarimetric tube and take the rotation at 25 C the specific rotation [α]_D²⁵ of the hydrochloride falls between -33.0 and -35.5 (The factor ephedrine to ephedrine hydrochloride is 1.22. The weight of the hydrochloride should be corrected for the water in the ephedrine by dividing the calculated weight by the percentage of ephedrine obtained in the titration).

Dissolve about 0.2 Gm of ephedrine hemihydrate, accurately weighed in 5 cc of neutralized alcohol add 5 drops of bromocresol green solution and an excess of tenth normal hydrochloric acid and titrate the excess using tenth normal sodium hydroxide solution the acid used in neutralizing the ephedrine is equivalent to not less than 94 per cent nor more than 96 per cent of ephedrine.

Dissolve about 0.2 Gm of ephedrine hemihydrate accurately weighed in a tared beaker in 10 cc of absolute ether evaporate spontaneously, dry the residue for 18 hours in a desiccator containing calcium chloride and ephedrine the temperature not being allowed to exceed 22 C the loss is not greater than 6 per cent nor less than 3 per cent.

Fit a 100 cc beaker with a cork stopper through which has been inserted a test tube 2 1/2 inches long and nine-sixteenths inch in diameter remove the stopper and accompanying test tube from the beaker transfer 5 Gm of ephedrine hemihydrate to the test tube melt the material by immersing the test tube in hot water cool the test tube and contents to about 30 C place the stopper and test tube in the beaker stir the supercooled liquid slowly using an appropriate Anschutz thermometer record the highest temperature obtained as the material congeals the congealing point is between 36 and 39.4 C.

Heat about 0.5 Gm of ephedrine hemihydrate accurately weighed in a platinum dish until constant weight is obtained the ash is less than 0.1 per cent.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
RAYMOND HERTWIG Secretary

NOT ACCEPTIBLE

OWNEN'S ORIGINAL LAXATIVE HEALTH BREAD

The Becker Bread Company of East St. Louis, Ill., sells bread named "Owens' Original Laxative Health Bread," which contains a substantial quantity of the purgative drug phenolphthalein. The label carries the statements:

Two slices a day keeps constipation away. Baked by secret formula formulated by Edward Owens International food specialist contains vegetables, fruits, soft wheat bran and pure honey endorsed by mothers everywhere.

Misbranded and Adulterated.—The appearance of the bread crumb indicates the presence of 'vegetables, fruits and wheat bran, but neither the appearance nor flavor discloses to the unsuspecting consumer the undeclared drug ingredient phenolphthalein, a well known purgative. The presence of the drug is readily demonstrated by the addition of alkali solution to the crumb producing a brilliant red color. The bread is adulterated and misbranded under the General Food and Drug Law of the State of Illinois and passing in interstate commerce, of the federal Food and Drugs Act.

Medicated Foods to Be Condemned.—The medication of a common food such as bread with the drug phenolphthalein must be viewed with apprehension and concern. This drugged bread cannot be distinguished from nondrugged breads. The label does not warn the consumer of the drug content. Prominent label declaration of the drug, however, would not prevent possible harm that may arise from continued use of the article. Addition of drugs to common foods tends to promote indiscriminate self medication and is to be unqualifiedly condemned as a menace to public health.

Discussion of Label.—The prominent claim "2 slices a day keeps constipation away" gives false assurance that this bread will prevent constipation whatever the cause. Continuous use of a purgative such as phenolphthalein may lead eventually to more serious chronic constipation, owing to decreasing response

of the bowel. The latter state is worse for the individual than the former. The drug-laxative habit is to be shunned by those desiring to protect health. Those suffering from constipation not readily yielding to a well balanced diet containing substantial indigestible bulk should consult a competent physician.

The statement "Baked by secret formula, formulated by Edward Owens, International Food Specialist" enshrouds the product in mystery and leads the easily credulous to believe that the bread has special merit because devised by the allegedly famous 'food specialist' Edward Owens. Edward Owens is unknown among recognized authorities in foods and nutrition.

The unsupported vague allegation "Endorsed by mothers undeservingly induces confidence in the bread on the part of persons not suspecting the true nature and possible harmfulness of the food. No bread warrants the misleading designation 'health bread'. No one food is capable of giving or producing health. The entire well balanced diet is only one of the many essentials for health.

Medicated bread such as this is potentially harmful to public health and should be eliminated from the market by government agencies having jurisdiction. The advertising is distinctly detrimental to public welfare and proper and honest advertising practices of the many food merchandisers who are earnestly attempting to serve the public ethically.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THEIR PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

WARRANTY SIEVED APPLES

Manufacturer.—The Nielsen Corporation, Ltd., Oakland Calif.

Description.—Sieved apples prepared by efficient methods for retention in high degree of the natural mineral and vitamin values. No added sugar or salt.

Manufacturer.—Purchased canned peeled, quartered apples are used. Brown spots or other undesirable portions are eliminated, and the subsequent processing and canning are essentially the same as described for Warranty Sieved Spinach (THE JOURNAL, Feb. 2 1935 p. 399).

Analysis (submitted by manufacturer) —	per cent
Moisture	88.8
Total solids	11.2
Ash	0.3
Sodium chloride	0.1
Fat (ether extract)	0.2
Protein (N X 6.25)	6.8
Reducing sugars as invert sugar	0.7
Sucrose	0.6
Crude fiber	9.7
Carbohydrates other than crude fiber (by difference)	0.3
Titratable acidity as malic acid	

Calories.—0.4 per gram 11 per ounce

Retention.—The method of preparation and processing insures the retention in high degree of the natural vitamin values.

Claims of Manufacturer.—Specially intended for infants, children and convalescents and for special smooth diets. Only warming is required for serving.

18-K BRAND FANCY MIXED VEGETABLES

Distributor.—Winston and Newell Company, Minneapolis

Packer.—The Larsen Company, Green Bay, Wis.

Description.—Mixture of carrots, potatoes, celery, green beans, cabbage, peas, corn, lima beans, onions, sweet peppers, salt and water prepared by efficient methods for retention in high degree of the natural mineral and vitamin values of the raw vegetables the same as Larsen's Veg-All—"A Magic Garden" for Soup, Salads, Vegetable Dishes (THE JOURNAL, Aug. 12 1933, p. 525).

THE ATLANTIC CITY SESSION

AMERICAN MEDICAL ASSOCIATION, EIGHTY SIXTH ANNUAL SESSION
CANADIAN MEDICAL ASSOCIATION, SIXTY SIXTH ANNUAL SESSION

ATLANTIC CITY, NEW JERSEY, JUNE 10 14, 1935

OFFICIAL CALL

TO THE OFFICERS, FELLOWS AND MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

The eighty-sixth annual session of the American Medical Association will be held in Atlantic City, June 10-14, 1935

The House of Delegates will convene at 10 a m, Monday, June 10 In the House the representation of the various constituent associations for 1935, 1936 and 1937 is as follows

Alabama	2	New Hampshire	1
Arizona	1	New Jersey	4
Arkansas	2	New Mexico	1
California	7	New York	17
Colorado	2	North Carolina	2
Connecticut	2	North Dakota	1
Delaware	1	Ohio	7
District of Columbia	1	Oklahoma	3
Florida	2	Oregon	1
Georgia	3	Pennsylvania	11
Idaho	1	Rhode Island	1
Illinois	9	South Carolina	2
Indiana	4	South Dakota	1
Iowa	3	Tennessee	3
Kansas	2	Texas	6
Kentucky	3	Utah	1

Maine	1	Virginia	3
Maryland	2	Washington	2
Massachusetts	6	West Virginia	2
Michigan	5	Wisconsin	3
Minnesota	3	Wyoming	1
Mississippi	2	Alaska	1
Missouri	5	Hawaii	1
Montana	1	Isthmian Canal Zone	1
Nebraska	2	Philippine Islands	1
Nevada	1	Puerto Rico	1

The fifteen scientific sections of the American Medical Association, the Medical Corps of the Army, the Medical Corps of the Navy and the Public Health Service are entitled to one delegate each

The Scientific Assembly of the Association will open with the general meeting to be held at 8 p m Tuesday, June 11 The sections will meet Wednesday Thursday and Friday, June 12, 13 and 14 as follows

CONVENING AT 9 A M THE SECTIONS ON

Obstetrics	Gynecology	and	Pathology and Physiology
Abdominal Surgery			Preventive and Industrial Medicine and Public Health
Pediatrics			
Laryngology, Otolaryngology and Rhinology			Urology
Miscellaneous Topics	Session on Anesthesia	Session on	Orthopedic Surgery
History of Medicine	Session on Military Medicine		

CONVENING AT 2 P M THE SECTIONS ON

Practice of Medicine	Nervous and Mental Diseases
Surgery, General and Abdominal	Dermatology and Syphilology
Ophthalmology	Gastro Enterology and Proctology
Pharmacology and Therapeutics	Radiology

The Registration Department will be open from 8 30 a m until 5 30 p m, Monday Tuesday Wednesday and Thursday, June 10 11, 12 and 13 and from 8 30 a m to 12 noon Friday, June 14

WALTER L. BIERING President
F C WARRSHILS Speaker House of Delegates
OLIN WEST Secretary

MEMBERS OF THE HOUSE OF DELEGATES

A Preliminary Roster of the Legislative Body of the American Medical Association

The list of members of the House of Delegates for the session is incomplete, as a number of the state associations are yet to hold their meetings at which delegates will be elected The following is a list of the holdover members of the House of Delegates and of the newly elected members who have been reported to the Secretary in time to be included

ATLANTIC CITY, 1935—THE PLAYGROUND OF THE WORLD

By Harry M. Resnick

No phrase aptly describes the seven mile strip of sand off the New Jersey coast that has become famous the world over as Atlantic City. Bountifully supplied with natural advantages of climate and location, Atlantic City has developed from a small fishing village to one of the greatest health and pleasure resorts of all times.

Always a favorite of vacationists the glamorous city by the sea offers more diversions to visitors than any other city of its size in the world. Visitors can find practically any type of activity desired. Those seeking rest and relaxation can be rolled along the Boardwalk in wheel chairs, relax on benches

situated along the ocean rail, recline on the comfortable sun decks of the piers well out over the ocean, or loaf in the sunshine on the beach front hotel decks that afford an unobstructed view of the surf and the Boardwalk.

Majestic sailing yachts, speedboats, motor launches, canoes and other craft dot the waters of Atlantic City's Inlet, where they pick up passengers either for a cruise out over the ocean or a trip along the comparatively calm waters of the Thoroughfare that separates the resort from the mainland.

At the Inlet, giant sea planes make regular flights over the island to afford passengers an opportunity to see Atlantic City from the air. Land planes make a similar flight from the Municipal Airport where giant ships from all over the country are landing at periodic intervals.

Sportsmen come from all points of the compass to enjoy the deep sea fishing off Atlantic City's coast. The giant tuna and the elusive sailfish are among the denizens of the deep that fall victim to the skill of the fisherman. Inland waters near the resort offer less hazardous but none the less exciting sport for the less daring nimrod. Qualified guides bait the hooks and remove fish that are caught for those who desire to fish without any discomfort.

GOLF COURSES

Three splendid golf courses are within easy distance. The Linwood and Northfield country clubs and the Seaview golf club are just a few minutes' ride from Atlantic City, and there are municipally owned and conditioned tennis courts, both at the Inlet and at the Airport.

Horseback riding can be enjoyed along the beach before and after the bathing hours, and at all times on the specially constructed track opposite the Heinz Pier. Saddle horses, pony carts and saddle ponies for the children are always available.

THE AMUSEMENT PIERS

No one who has been to Atlantic City can ever forget the amusement piers which extend in some instances almost half a mile out into the ocean. The most famous is the Steel Pier, where the greatest variety of attractions can be witnessed for a nominal admission.

It is impossible to take in all the Steel Pier's features in one visit of an entire day on the structure. Included in the program are famous stars of the stage screen and radio, vaudeville three motion picture houses, diving horses, acrobats of the tight rope who perform hundreds of feet above the ocean, minstrels, dancing, Hawaiian orchestras, high diving exhibitions, water sports and a variety of interesting exhibits.

THE DEEP SEA NET HALL

One of the most fascinating spectacles that Atlantic City offers is the deep sea net haul which takes place at the extreme end of Young's Million Dollar Pier, more than 2,000 feet out over the ocean. Twice daily at noon and at 4 o'clock in the afternoon, the nets are hauled up to reveal all sorts of specimens of deep sea life. Aquariums in Philadelphia, New York and Chicago feature strange creatures of the ocean that were caught in these nets, and the pier's own aquariums are always filled with fish of every description.

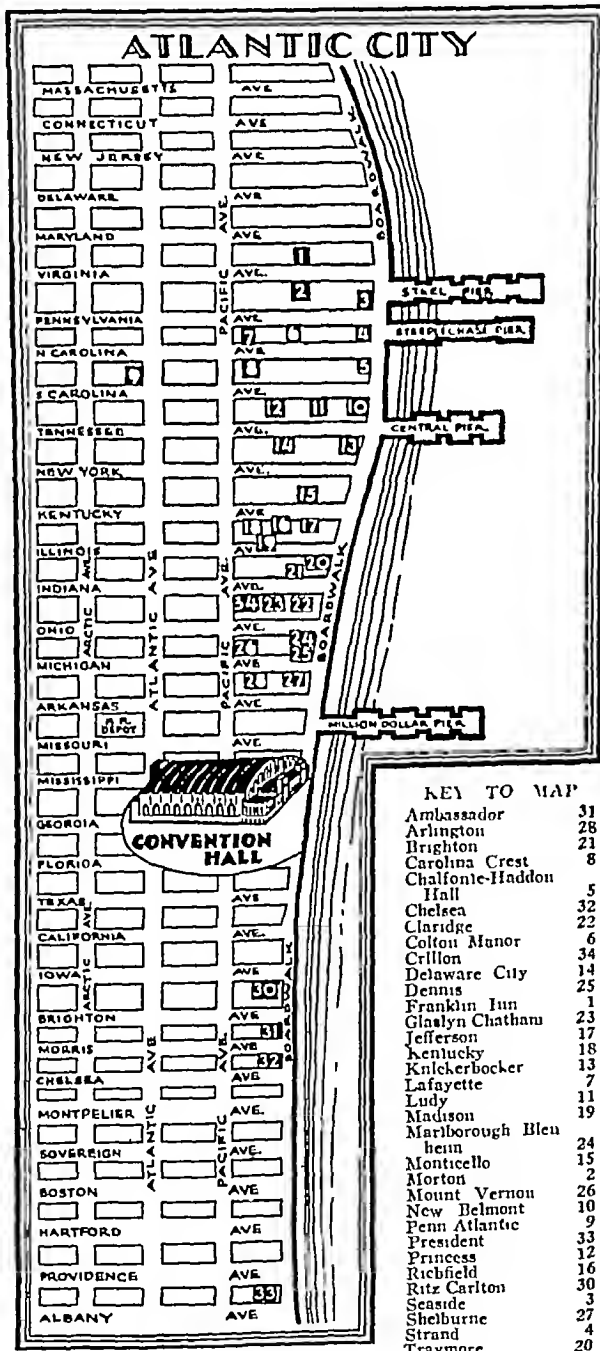

Wild West shows with real cowboys and Indians, motion pictures, dancing and a variety of other attractions are presented along with the net hauls.

Scores of the latest amusement devices for children are presented at the Steeplechase Pier, which features one of Atlantic City's two over the ocean restaurants. The other is situated on the Garden Pier, which also houses a variety of amusement attractions.

Lovers of art will enjoy a morning or afternoon on the historic Heinz Pier, where rare paintings, statuary and the unusual finds of scientific excavation parties are on exhibition.

Four ornate motion picture houses are situated on the Boardwalk and many more are strung along Atlantic Avenue, the main street of the shopping district. Legitimate plays are pre-

MAP OF ATLANTIC CITY

Convention Hall is located on the Boardwalk between Mississippi and Georgia avenues.

sented at the Garden Pier Theater, and special productions are offered at the Globe Theater, another Boardwalk playhouse

Restaurants, hotel grills and supper clubs have taken on a new gaiety and lovers of good food have a wide range of choice. Famous dance orchestras and special programs of entertainment are featured in the hotel grills

LOWER PRICES

The rates of Atlantic City's magnificent hotels are lower now than they have been within the last twenty years. The same is true of restaurants and places of amusements for the city has answered the challenge of Florida resorts by the slashing of prices

The new spirit is reflected in the array of smart shops that stretch along the Boardwalk for miles. Merchandise from all corners of the globe is displayed at prices that are often lower than those charged for similar articles in the visitor's home city

of the treacherous Brigantine shoals. During certain hours ascent to the top of the lighthouse is permitted, and the breathtaking view out over the ocean is well worth the climb

THE HUGE CONVENTION HALL

To the distinction it has gained as the greatest health and pleasure resort Atlantic City may add the claim of having the largest building of its kind in the world. The Convention Hall where the American Medical Association meeting will be held has been erected on a more lavish scale than has ever before been attempted in any country

The Convention Hall, which fronts on the Boardwalk between Georgia and Mississippi avenues, is 350 feet wide by 650 feet deep and covers an area of seven acres. It provides a total seating capacity of nearly 75,000, the main auditorium alone having a seating capacity of 41,000. Atlantic City has a permanent population of 65,000, and every person residing within its

AIRPLANE VIEW OF ATLANTIC CITY

BEAUTIFUL HOMES

A visit to Atlantic City is not complete without seeing its two residential suburbs Ventnor and Margate where all manner of beautiful homes can be seen. Colonial mansions, Spanish villas, Italian triumphs of architectural beauty set in the center of sweeping lawns and typical American homes vie for attention with beautiful shrubbery and flower gardens

It is to Ventnor and Margate, and the Chelsea section of Atlantic City that cottagers move for the summer months creating a social whirl of their own

Names that are famous in the annals of society statesmanship the theater art and politics are listed among those who make up the cottage colonies

THE ABSECON LIGHTHOUSE

Of endless interest to visitors is the famous Absecon Lighthouse which for years has served as a beacon to warn mariners

limits could be provided with seating accommodations in this structure with room to spare

Huge as is this monument to the progress of the Playground of the World it is none too large, for during the summer season the resort frequently entertains between 350,000 and 400,000 visitors

The floor of the main auditorium is 168,000 square feet in area while an additional space of 100,000 square feet is provided on the ground floor. Adjacent to the main auditorium and fronting the Boardwalk is another large hall measuring 130 by 185 feet which has a seating capacity of approximately 5,000 and also has a stage and committee rooms. A large arched loggia 12 feet wide, overlooking the ocean fronts this hall

In front of the Convention Hall are two splendidly equipped bath houses 60 by 150 feet in area. Branch lines of the Pennsylvania-Reading Seashore Lines run direct to the Convention

Hall on either side, making it possible should the need present itself, to discharge passengers almost on the berth itself.

A unique feature of the main auditorium is a floor space of 90 by 200 feet, which can be converted into an ice skating rink in a short time. Hockey has been one of the sports featured at the Convention Hall during the past two winters and the Atlantic City Sea Gulls won this year the national amateur hockey title. The ice in the rink can be melted in a few hours and the floor restored to its former condition.

THE MAIN AUDITORIUM

The immensity of the main auditorium may be envisioned from the fact that a thirteen-story building 500 feet in length and 200 feet wide might be erected within its walls leaving a space of 100 feet on all four sides. Football is played regularly at night in this mammoth hall on a regulation playing field with special illumination that gives the entire place a daylight appearance.

Within the main auditorium also has been constructed the largest stage in the world. It is 110 feet in width 85 feet in depth and measures 165 feet between the wings. It has all modern properties, full electrical equipment and dressing room facilities, and on it may be shown the most spectacular of productions.

THE LARGEST PIPE ORGAN

The largest pipe organ in the world both in size and in power is housed in the main auditorium. Perfect acoustics comprise another feature. Despite the auditorium's immense proportions the organ pipes have been so arranged at both sides of the stage and along the high vaulted ceiling that the entire auditorium can be flooded with melody graded to meet the needs of either large or small assemblages.

The lighting of the Convention Hall is a triumph of color and illumination. The hues of the sea and the sky mingled with gold, predominate. Through the medium of an original

are faced with marble and ornamental bronze, and from the arcade leads an entrance, 50 feet in width, to the interior of the Convention Hall.

PARKING SPACE

Approximately 400 automobiles may be parked on the ground floor of this great structure. Terraced sidewalks have been provided on both Georgia Avenue and Mississippi Avenue in addition to the ramp inclines from the ground. By this means the huge crowds that on occasions fill the hall to capacity are handled with great dispatch.

THE VENTILATING SYSTEM

Heat and ventilation are important items in a great structure of this character. Direct radiation is used in the main entrance lobby and entrances on the sides of the building and is supplied by recirculating air warming units.

For the maintenance of the required vacuum in the heating returns and for the disposal of air and condensation, six vacuum pumps are provided. The temperature throughout the entire structure is automatically controlled. Ventilation is provided by thirty-one motor driven fans, with an hourly capacity of 1,600 tons. There are also seventy five vent fans capable of discharging 2,900 tons of air an hour. Seventy two per cent of the air supplied to the building is for the main auditorium.

Elevators capable of handling all kinds of heavy equipment have been installed. There are two large freight lifts of the vertical steel screw type, each having a capacity of 50,000 pounds in addition to a freight elevator of 4,000 pounds capacity for trunks and light freight and a passenger elevator lifting 2,000 pounds at the rate of 300 feet a minute.

Three Sterling water tube boilers of 1,490 rated horsepower have been installed. This boiler plant provides steam for heating for hot water and for exhibition purposes. The oil fuel

THE CONVENTION HALL WHICH WILL HOUSE ALL SCIENTIFIC MEETINGS AND EXHIBITS

principle, the lighting of the stage and auditorium has been designed to permit not only the usual projection and special display of feature objects but also an unlimited showing of color effects.

The lobby leading to the Convention Hall has a vaulted passage 125 feet in length and 50 feet in width. The walls are of limestone, with a ceiling of Gustavino tile and two-tone terrazzo floor, with appropriate bronze enframements round the windows. Leading directly from this lobby and connecting with ramps to the upper and lower levels of the auditorium are roomy corridors.

THE ARCADE

An arcade containing fourteen finely finished stores stretches along the entire Boardwalk front of this structure. The stores

is stored in underground tanks, and coal bunkers have been provided so that if necessary a change may be made from oil to coal as fuel.

EQUIPMENT FOR THE PRESS

Atlantic City has exceptional advantages for the dissemination of news of national importance. With an Associated Press outlet in the Atlantic City Press-Union newspapers correspondents on the scene from New York and Philadelphia newspapers and a 50,000-watt radio station of the Columbia chain, the resort gets unusual news coverage.

The Atlantic City Press Commission composed of six trained newspapermen will place at the disposal of convention gatherings the facilities of City Press Headquarters, which is equipped for national distribution of news and pictures.

TRANSPORTATION FACILITIES

The unequaled transportation facilities of Atlantic City, which make it possible for millions of persons to pour in and out of the resort by motor train, bus and airplane, are described by Thomas Hesselton executive manager of the Atlantic City Chamber of Commerce. No other resort in the world has such highways leading into it, and to no other resort is it easier for wheels to turn. The world's best known highway, the "White Horse Pike," now has a twin the "Black Horse Pike," to assist in aiding the millions to move in and out of Atlantic City. The Delaware River is crossed by no less than five highway bridges from Philadelphia north and

ROLLING CHAIRS

Special rates will be granted on chairs of the Shill Rolling Chair Company to persons wearing Convention Badges Between Seaside Hotel and Convention Hall or between Hotel Chelsea and Convention Hall, in either direction, the charge will be 50 cents for one, two or three passengers

JITNEY SERVICE

The fare along Pacific Avenue from Maine Avenue to Jackson Avenue, the border of Ventnor, is 10 cents, delivering a passenger at the Boardwalk or elsewhere on a cross avenue is 10 cents extra. Twelve tickets are sold for \$1

THE CONVENTION HALL AND THE BOARDWALK AT NIGHT

spanned by five important ferry routes from Philadelphia, south, draining the important areas to the South and West. In 1919 Atlantic City recognized the importance of commercial aviation and dedicated to it the first municipal airport in the world. By plane Atlantic City is five hours from Chicago, eight from Kansas City, one to Newark, two to Washington and less than three to Pittsburgh. The resort's airport is one of the finest in the country.

GARAGE FOR AUTOMOBILES UNDER THE CONVENTION HALL

There is a garage located in the Convention Hall, directly under the arena and the assembly hall, which will be a real convenience to those physicians who are driving to the annual session.

This garage accommodates 500 cars. The charge will be \$2.50 for the period of the convention.

TRANSPORTATION

Railroad Rates to Atlantic City

Special rates have been granted for the benefit of members of the American Medical Association and of the Canadian Medical Association and dependent members of their families who will attend the annual session at Atlantic City.

The Central, the New England, the Southeastern, the Southwestern, the Transcontinental, the Trunk Line and the Western Passenger Associations, as well as the Eastern and Western Lines of the Canadian Passenger Association, have granted a rate of one and one-third fares.

To have the benefit of a return rate of one-third fare, it will be necessary for each member to secure a **CERTIFICATE** from the railroad ticket agent when he purchases his ticket to Atlantic City. The certificate must be certified to by the Secretary of the American Medical Association, which may be done at the Registration Bureau, to be located in the Convention Hall in Atlantic City, and must then be validated by a representative of the railroads. When the certificate is so certified and validated, it will entitle its holder to purchase a return ticket to his home over the same route traveled to Atlantic City at one-third fare.

If the ticket agent at the member's home station does not have the certificate, he will furnish information as to where it may be obtained.

The certificate is *not* a receipt for money paid for a ticket, nor will a receipt entitle its holder to secure a return trip ticket

at a reduced rate. Be sure to ask the ticket agent for a **CERTIFICATE**.

The dates of sale of tickets to Atlantic City will be June 6 to 12 in the territory of the Eastern Lines of the Canadian Passenger Association and in the territories of the Central Passenger Association, the New England Passenger Association, the Southeastern Passenger Association and the Trunk Line Association from Arkansas, Kansas, Louisiana and Missouri, as well as Natchez, Miss., and Memphis, Tenn., in the territory of the Southwestern Passenger Association, and from Illinois, Iowa, Kansas, Manitoba, Minnesota, Missouri, Nebraska, northern Michigan and Wisconsin, as well as Julesburg, Colo., in the territories of the Transcontinental and Western Passenger Associations and from Saskatchewan, Manitoba and Ontario (west of Port Arthur and Armstrong) in the territory of the Western Lines of the Canadian Passenger Association.

In the territories of the Southwestern, Transcontinental and Western Passenger Associations and of the Western Lines of the Canadian Passenger Association, the dates of sale of tickets from Alberta, Colorado (except Julesburg), North Dakota, South Dakota, Oklahoma, Texas and Wyoming will be June 5 to 11 from Montana and southern Idaho, June 4 to 10 and from Arizona, British Columbia, California, Nevada, New Mexico, northern Idaho, Oregon, Utah and Washington, May 29 to June 11.

Certificates properly certified and validated will be honored for purchasing tickets for the return journey at one third fare up to and including June 18. No refund of fare will be made on account of failure to present validated certificate when purchasing return ticket. The return ticket must be used over the same route as that traveled going to Atlantic City.

When you purchase your ticket to Atlantic City secure from the railroad ticket agent a CERTIFICATE which, when properly certified to and validated will entitle you to purchase

the special rate of one and one third fares or the summer excursion fares

Air Travel

Detailed information on any air or air-rail trip from any part of the United States to Atlantic City will be gladly furnished by any United Air Lines ticket office or through its Chicago office at 400 South Michigan Avenue, or from any other airline ticket office, Postal Telegraph or Western Union office or travel bureau.

DISEASES

a return ticket to your home, over the same route traveled to Atlantic City, at one third the fare paid for your ticket to Atlantic City.

BE SURE TO ASK YOUR RAILROAD TICKET AGENT FOR A CERTIFICATE WHEN PURCHASING YOUR TICKET TO ATLANTIC CITY

Summer Excursion Fares

Summer excursion fares in the territories of the Transcontinental and Western Passenger Associations and of the Western Lines of the Canadian Passenger Association which in some instances are on a lower basis than convention fares, will apply from some of the Western states, and members are urged to confer with their ticket agents as to which fare is the lower—

REGISTRATION

The Bureau of Registration will be located in the Convention Hall Boardwalk between Mississippi and Georgia avenues. Members of the Subcommittee on Registration of the Local Committee on Arrangements will be on hand to assist those who desire to register. A branch postoffice in charge of government postoffice officials will be available for visitors and an information bureau will be operated in connection with the Bureau of Registration.

Who May Register

Only Fellows, Affiliate, Associate and Honorary Fellows, and Invited Guests may register and take part in the work of the sections. Fellows of the Scientific Assembly are those who have on the prescribed form, applied for Fellowship subscribed

THE HOSPITAL LABORATORY

Views of Atlantic City Hospital

ATLANTIC CITY HOSPITAL OF 316 BEDS

to THE JOURNAL, and paid their Fellowship dues for the current year. The annual Fellowship dues provide a subscription to THE JOURNAL for one year. Fellowship cards are sent to all Fellows after payment of annual dues and these cards should be presented at the registration window. Any who have not received cards for 1935 should secure them at once by writing to the American Medical Association, 535 North Dearborn Street, Chicago.

that pocket cards may be secured and brought to Atlantic City so that registration can be more easily and more promptly effected.

Application forms may be had on request.

Those subscribers to THE JOURNAL who have not received pocket cards for 1935 should write to the American Medical Association for application blanks and information as to further requirements.

Members in Good Standing Eligible to Fellowship in the Association

Members in good standing in component county medical societies are members of constituent state associations and of the American Medical Association. All members in good standing may apply for Fellowship in the Scientific Assembly and are urged to qualify as Fellows before leaving home in order

Register Early

Fellows living in Atlantic City as well as all other Fellows who are in Atlantic City on Monday and Tuesday, should register as early as possible. The names of those who register will appear in the issue of the *Daily Bulletin* appearing the next day and this will enable visiting physicians to find friends if they have registered.

Suggestions That Will Facilitate Registration

Fellows should fill out completely the spaces on both sections of the front of the *white* registration card, which will be found on the tables in front of the Registration Bureau

Physicians who desire to qualify as Fellows should fill out completely the spaces on both sections of the front of the *blue* registration card and sign the application on the back. These cards will be found on the tables

Entries on the registration cards should be written plainly, or printed as the cards are given to the printer to use as "copy" for the *Daily Bulletin* published on Tuesday, Wednesday, Thursday and Friday of the week of the session

Fellows who have their pocket cards with them can be registered with little or no delay. They should present the filled out *white* registration card, together with their pocket cards, at one of the windows marked "Registration by Pocket Card". There the clerk will compare the two cards, stamp the pocket card and return it, and supply the Fellow with a badge, a copy of the official program and other printed matter of interest to those attending the annual session

As previously stated, it will assist in registering if those who desire to qualify as Fellows will file their applications and qualify as Fellows by writing directly to the American Medical Association, 535 North Dearborn Street, Chicago, so that their Fellowship may be entered not later than May 20. Any applications that are received later than May 20 will be given prompt attention, but the Fellowship pocket card may not reach the applicant in time for him to register at the Atlantic City session

It will be possible for members of the organization to qualify as Fellows at Atlantic City. In order to do this, applicants for Fellowship will be required to fill out both sections of the front of the *blue* registration card and to sign the formal application that is printed on the reverse side of the card. As already stated, registration can be effected more easily and more promptly if members will qualify as Fellows before leaving home

It is suggested that those who apply for Fellowship at Atlantic City provide themselves before leaving home with certificates signed by the secretaries of their state associations attesting that they are members in good standing in state and county branches of the organization. A state membership card for 1935 will be acceptable. The certificate or membership card should be presented along with the filled in *blue* registration card at the window in the booth marked "Applicants for Fellowship and Invited Guests"

Registration for General Officers and Delegates at the Ambassador Hotel

General Officers of the American Medical Association and members of the House of Delegates may register for the Scientific Assembly at a booth near the Renaissance Room of the Ambassador Hotel. This arrangement is made for the convenience of the members of the House of Delegates which will convene on Monday morning at 10 o'clock in the Renaissance Room of the Ambassador Hotel. Delegates are requested to register for the Scientific Assembly before presenting credentials to the Reference Committee on Credentials of the House of Delegates. Registration of delegates for the Scientific Assembly will begin at 8 o'clock Monday morning, June 10, and delegates are urged to register early so that all members of the House of Delegates may be seated in time for the opening session of the House.

Registration for Members of Canadian Medical Association

Provision will be made for the registration of the members of the Canadian Medical Association under the direction of its officers. The members of the Canadian Medical Association who are registered may attend and participate in the work of the scientific sections.

ATLANTIC CITY HOTELS

A list of Atlantic City hotels is presented for the benefit of those who expect to attend the annual session of the American Medical Association, June 10-14. Dr. William Edgar Darnall is the chairman of the Subcommittee on Hotels of the Local Committee on Arrangements and may be addressed at 16 Central Pier, Atlantic City, N. J. The advertising announcement and coupon for reservations appear on advertising page 115 of this issue.

Women Physicians of American Medical Association

The women physicians of the American Medical Association will meet socially in Atlantic City on the Sunday and Monday preceding the opening of the session, stopping en route in Philadelphia on Saturday June 8, to attend a special program at the Woman's Medical College of Pennsylvania.

While in Atlantic City the medical women will make the Marlborough-Blenheim the headquarters for their various social activities which, during the session of the American Medical Association, will be confined strictly to meal hours, as these dining programs have been found so enjoyable at previous sessions. On Sunday and Monday, social affairs, including sight seeing trips will be continued throughout the day

The Federation of Medical Women of Canada is uniting with the American women to make these meetings successful

Interesting programs have been arranged at which the following women physicians will preside

SUNDAY, JUNE 9

Luncheon. Ellen C Potter (New Jersey)
Supper Ella Coughlan (New Jersey)

MRS SAMUEL L SALASIN,
General Chairman of Arrangements
MRS CARL A SURRAN,
Chairman of Entertainment.

GOLF TOURNAMENT

The twenty-first annual tournament of the American Medical Golfing Association will be held at the Northfield Country Club Atlantic City Monday, June 10 A thirty-six hole competition will be played for the seventy prizes offered in nine events This includes the championship event which has as its major prize the famous Will Walter Trophy awarded since 1923 for low gross thirty-six holes This trophy designed by Edgar Millar and executed by the Cellini Shop Evanston Ill symbolizes the evolution of medicine.

HANDLES DEPICT HISTORY OF MEDICINE

The first handle depicts the age of primitive ignorance with shaman witch doctor spells and the invocation of nature gods to cure ailing mankind from antiquity to 500 B C The second handle shows the age of Greek thinkers bearing the serpents symbolic of Aesculapius god of medicine—an age of thought and research from 500 B C to 640 A D The third handle represents the age of medieval superstition from 640 A D to 1500 A D with an astrologer the physician common to the dark ages The fire of incantation rises behind the figure as he traces a cabalistic sign in the air The fourth handle depicts the age of modern medical research from the

Renaissance to modern time, with increasing light spreading from a figure symbolic of an enlarging vision

Winners since the cup was placed in competition have been Drs E. A Searioth, San Francisco 1923 George McKee, Pittsburgh, 1924, Homer Nicoll, Chicago, 1925 S M Hill Dallas Texas 1926 George McKee 1927 Walter Shelden Rochester Minn 1928, John Loudon Yakima, Wash, 1929 and 1930 George McKee 1931 S M Hill 1932 Mark Bach Milwaukee, 1933 and John Loudon Yakima, Wash 1934 (third time)

OTHER EVENTS—SEVENTY PRIZES

Other events and trophies include the Association Handicap Championship thirty-six holes net with the Detroit Trophy, the Championship Flight first gross thirty-six holes, with the St. Louis Trophy the Championship Flight, first net, thirty-six holes the President's Trophy the Eighteen Hole Gross Championship with the Golden State Trophy, the Eighteen Hole Handicap Championship with the Ben Thomas Trophy the Maturity Event with the Minneapolis Trophy the "Oldguard" Championship with the Wendell Phillips Trophy the Kickers Handicap with the Wisconsin Trophy

A M G A HAS ELEVEN HUNDRED MEMBERS

Dr Charles Lukens of Toledo is president, Drs C H Henninger of Pittsburgh and John B Morgan of Cleveland are vice presidents of the American Medical Golfing Association which has a total membership of approximately 1100 representing every state in the Union. All male Fellows of the American Medical Association are eligible to membership. A cordial invitation is extended to every medical golfer to write

TEERING OFF AT THE NORTHFIELD COUNTRY CLUB
ATLANTIC CITY

the executive secretary Bill Burns 4421 Woodward Avenue Detroit for an application blank. An enjoyable day on June 10 will be the result.

AMERICAN-CANADIAN MEDICAL COLLEERS TO PLAY

International golf will be played at Atlantic City June 10 when members of the American Medical Golfing Association and golf enthusiasts of the Canadian Medical Association join forces at Northfield Country Club.

The A M G A's invitation to the Canadian Medical Association to hold a joint tournament this year has been accepted by Dr T C Routley, general secretary of the Canadian Medical Association, who replied "I am sure our Canadian colleagues will appreciate highly the honor you have done them in asking them to be present at the twenty first annual tournament of the American Medical Golfing Association."

TWO ADDITIONAL EVENTS

Two additional events will be added to the day's already generous program of nine events and seventy prizes.

1 The International Event, featuring the 'President's Cup' a new trophy presented by Dr Charles Lukens of Toledo, Ohio and nine other American prizes for our Canadian friends to carry back home.

2 The Canadian Event, featuring the "Ontario Cup," or championship trophy, and the other prizes of the Canadian Medical Association.

MANY FOURSOMES COMBINING CANADIAN
AND AMERICAN PLAYERS

Many American golfers having medical friends in Canada are arranging matches for the international medical golf tournament of June 10. It is expected that 200 players will tee off between 6 a m and 3 p m in this thirty-six hole and eighteen hole competition. The Atlantic City committee has arranged that free busses will leave from Haddon Hall from the Shelburne Hotel and from the Ambassador Hotel at 8 30 a m and will return from Northfield in the evening at 10 30. Dinner will be served at 7 p m with Dr Frank A Kelly of Detroit as toastmaster followed by distribution of trophies and prizes by Dr Walt P Conaway chairman of the Atlantic City Golf Committee.

For entry blanks write Bill Burns, Executive Secretary 4421 Woodward Avenue, Detroit.

THE PROGRAMS OF THE SECTIONS

Outline of the Scientific Proceedings—The Preliminary Program and the Official Program

The following papers are announced to be read before the various sections. The order here is not necessarily the order that will be followed in the Official Program nor is the list complete. The Official Program will be similar to the pro-

grams issued in previous years and will contain the final program of each section with abstracts of the papers, as well as lists of committees program of the Opening General Meeting list of entertainments map of Atlantic City, and other information. To prevent misunderstandings and protect the interest of advertisers it is here announced that this Official Program will contain no advertisements. It is copyrighted by the American Medical Association and will not be distributed before the session. A copy will be given to each Fellow on registration.

- Chairman—J F BURGESS, Montreal Que
Secretary—PAUL POIRIER Montreal Que

Wednesday, June 12—2 p m

- Chairman's Address (A M A) Observations on the Therapy of Acne Vulgaris

- JEFFREY C MICHAEL, Houston, Texas
- The So Called Mosaic Fungus as an Interacellular Deposit of Cholesterol Crystals (Lantern Demonstration)
A M DAVIDSON and P H GREGORY Winnipeg Manit
Discussion to be opened by JOHN GODWIN DOWLING, Boston
- Rosacea Interpreted as a Bacterid from Focal Infection (Lantern Demonstration)
HERMANN FRIT ELIZABETH ANN LASZLO and FRANK VERO New York
Discussion to be opened by SAMUEL AYRES JR, Los Angeles

- Lichen Simplex Chronicus (Lantern Demonstration)
D F H CLEVELAND, Vancouver B C
- Functional Studies in Patients with the Neurodermatoses (Lantern Demonstration)
J M VAN DE ERVE Charleston, S C, and S WILLIAM BECKER, Chicago
Discussion on papers of DR CLEVELAND and DR VAN DE ERVE and BECKER to be opened by PHILIP BURNETT, Montreal, Que and PAUL A O'LEARY Rochester, Minn

- An 'Office' Technique of Treating Functional Neuroses as Complications of Organic Disease with Special Reference to the Dermatoneuroses (Lantern Demonstration)

- JOHN H STOKES, Philadelphia
Discussion to be opened by EARL D BOND, Philadelphia
- Histogenesis of Aberrant Lesions of Psoriasis (Lantern Demonstration)
PAUL D FOSTER, Los Angeles, and GEORGE M MACKEE, New York
Discussion to be opened by CLARK W FINNERUD, Chicago

Thursday, June 13—2 p m

- Chairman's Address (C M A) Chronic Glanders in Man (Lantern Demonstration) J F BURGESS Montreal, Que
- The Treatment of Early and Late Congenital Syphilis in Children The Results of Treatment in 521 Patients
FRANK R SMITH JR Baltimore
Discussion to be opened by E J TROW Toronto Ont

- A Study of Dementia Paralytica and Tabes with Reference to Precocious Development (Lantern Demonstration)
DUNCAN O POTTS, BURTON F BARNEY and Udo J WILLE Ann Arbor, Mich
Discussion to be opened by R E POWELL, Montreal Que
- Artificial Fever Therapy of Syphilis (Lantern Demonstration)
WALTER M SIMPSON Dayton, Ohio
Discussion to be opened by FRANK R MENAGH Detroit
- A Study of the Comparative Value of Bismuth and Mercury Compounds in the Treatment of Early Syphilis (Lantern Demonstration)
A BENSON CANNON and JOYCELYN H ROBERTSON, New York
Discussion to be opened by HAROLD ORR Edmonton, Alta
- Intradermal Test for Chancroids with Sterilized Pus from Chancroidal Buboos (Lantern Demonstration)
HAROLD N COLE and E A LEVIN, Cleveland
Discussion to be opened by ALBERIC MARIN, Montreal Que
- The Balanitides (Lantern Demonstration)
JOHN F MADDEN, St. Paul
Discussion to be opened by P H POIRIER, Montreal, Que

Friday, June 14—2 p m.

Election of Officers

- Congenital Atrophy of the Skin with Reticular Pigmentation Report of Two Cases M F ENGMAN JR, St. Louis
Discussion to be opened by H A DIXON, Toronto, Ont
- Fever Therapy of Mycosis Fungoides
J V KLAUDER, Philadelphia

- Discussion to be opened by W R JAFFREY, Hamilton, Ont

- Granuloma Coccidioides Report of Two Cases of a Chronic Hypertrophic Type (Lantern Demonstration)
J L PIRKIN and C F LEHMANN, San Antonio, Texas
Discussion to be opened by CHARLES C TOMLINSON Omaha

- Hodgkin's Disease of the Scalp (Lantern Demonstration)
N M WROG, Toronto Ont
Discussion to be opened by RICHARD W FOWLER, Richmond, Va

- Depth Dose Measurements for Dermatologic Roentgen Therapy (Lantern Demonstration)
GEORGE C ANDREWS and CARL B BRAESTRUP, New York
Discussion to be opened by ANTHONY C CIPOLLARO, New York

- Granuloma Annulare Report of Unusual Cases, with Remarks on the Histology of This Condition (Lantern Demonstration)
M H GOODMAN and LLOYD W KETRON Baltimore
Discussion to be opened by G S WILLIAMSON Ottawa, Ont

- The Relation of the Endocrine System to Dermatology
WAITER O TEICHMAN and FRANK J EICHENLAUB, Washington D C
Discussion to be opened by BARNEY USHER, Montreal Que

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit will occupy part of the main floor and the stage of the Atlantic City Auditorium with entrances from the Technical Exhibit near the registration desks. The same general arrangement of booths and decorations will be carried out as in former years. In addition to the group exhibits sponsored by the fifteen sections of the Scientific Assembly there will be several motion picture programs running simultaneously: symposium exhibits on cancer, tuberculosis and syphilis and special exhibits on obstetric and gynecologic hemorrhage, on the relation of psychiatry to the physician in general practice and on acute infections of the central nervous system in children, all under the direction of various section exhibit committees. The special exhibits subsidized by the Board of Trustees include diabetes, nutrition, prevention of asphyxial deaths and vaccines and serums.

Admission to the Scientific Exhibit will be limited to individuals wearing Fellowship or other badges of the convention and to guests to whom special cards of admission have been issued. The public will not be admitted to the exhibit.

Special Exhibit on Diabetes

The exhibit on diabetes is presented by a committee composed of E P Joslin, chairman, Boston, F G Banting, co chairman, Toronto, C H Best, Toronto, H F Root, Boston, R M Wilder, Rochester, Minn, and R T Woodyatt, Chicago.

The exhibit will include all phases of the subject under the following headings: History and statistics of diabetes, heredity, incidence and etiology, Physiology of diabetes, Pathology of diabetes, Treatment of diabetes (a) diet, (b) insulin, Insulin reactions, Complications in diabetes (a) coma, (b) tuberculosis, (c) arteriosclerosis, (d) pregnancy, Surgery in diabetes (a) anesthesia, (b) operations, (c) gangrene and its prevention, Diabetes economics, including diabetic camps, State and city diabetic programs.

In addition to continuous demonstrations on all of the foregoing subjects throughout the week there will be opportunity for conferences of small groups of individuals in an area adjoining the exhibit.

An outstanding group of individuals has consented to act as demonstrators.

Special Exhibit on Nutrition

The exhibit on nutrition is presented for the second time under the direction of a committee composed of Reginald Fitz, chairman, Boston, Walter C Alvarez, Rochester, Minn., and L H Newburgh, Ann Arbor. The exhibit will include nutrition in the hospital, showing the phase of the dietitian in the hospital organization, nutrition in the home, where the physician must act as dietitian, demonstration of special diets, a normal diet being used as a nucleus. A competent corps of demonstrators will be on hand continuously throughout the week.

Special Exhibit on Prevention of Asphyxial Deaths

The exhibit on prevention of asphyxial deaths is presented by the Committee on Scientific Exhibit of the Board of Trustees in cooperation with the Society for the Prevention of Asphyxial Deaths, under the auspices of a special exhibit committee composed of C L Jackson, chairman, Philadelphia, Harrison S Martland, Newark, N J, and R R Sayers, Washington, D C.

The exhibit, consisting of charts, posters, photographs, specimens, apparatus and motion pictures, will be presented under the following headings:

Asphyxial deaths from anesthesia
Asphyxial deaths from diphtheria
Asphyxial deaths from allergic shock
Asphyxial deaths from asphyxia neonatorum
Violent deaths from asphyxia
Oxygen and helium therapy
Prevention of asphyxial death by the community
Prevention of asphyxial deaths by organized medicine
Tracheotomy for obstructive laryngeal dyspnea

Demonstrations will be conducted continuously throughout the week in each booth. The following demonstrators have kindly consented to serve: Alvan L Barach, New York, C W Buckmaster, Yonkers, N Y, Jesse G M Bullock, New York, Paluel J Flagg, New York, Wheaton Fregeau, New York, Chevalier L Jackson, Philadelphia, John Francis McGrath, New York, Harrison S Martland, Newark, N J, Samuel Neffson, New York, Lawrence W Smith, New York, Warren T Vaughan, Richmond, J T Wilson and Robert A Wilson, Brooklyn.

In addition to demonstrations in the booths, there will be a special motion picture program in an area adjoining the exhibit

Special Exhibit on Vaccines and Serums

The exhibit on vaccines and serums is presented by a special committee under the joint auspices of the Committee on Scientific Exhibit of the Board of Trustees of the American Medical Association and the United States Public Health Service. The committee is composed of James P. Leake, Washington, D. C., William G. Workman, Washington, D. C., and Ralph C. Williams, chairman, Washington, D. C.

The exhibit will consist of charts, specimens, talks and demonstrations. It will be presented under seven headings with the following demonstrations:

Measles C. F. McKhann Boston
Rabies W. G. Workman Washington, D. C.
Typhoid Fever S. S. Cook Washington, D. C.
Diphtheria W. T. Harrison Washington, D. C.
Smallpox J. P. Leake, Washington, D. C.
Scarlet Fever
Tetanus R. H. Miller Boston

In spaces adjoining this material there will be additional exhibits on pneumonia, meningitis and poliomyelitis, presented by various individuals.

SECTION EXHIBITS

Section on Practice of Medicine

Section exhibit committee: IRVING S. WRIGHT, chairman, New York; RUSSELL L. HADEN, Cleveland; EUGENE S. KILGORE, San Francisco; L. G. ROWNTREE, Philadelphia; and D. SCLATER LEWIS, Montreal.

RUSSELL L. HADEN, Cleveland Clinic, Cleveland

Qualitative Variations in Neutrophilic Leukocytes Exhibit of natural color photomicrographs illustrating changes in shape of nucleus (Arnet, Schilling, Cooke and Ponder, and filament-nonfilament counts), variation in cytoplasmic granules ('toxic' or basophilic granulation) and other abnormalities of nucleus, granules and cytoplasm of the neutrophil.

CARL H. GREENE, J. RUSSELL TWISS and R. FRANKLIN CARTER, New York Post-Graduate Medical School, New York.

Diagnosis of Gallbladder Disease Exhibit of charts, specimens and a model illustrating the technique of biliary drainage, the pathologic observations and a comparative study of various diagnostic methods: history, cholecystography, and so on, in a series of cases of gallbladder disease.

ZACHARIAS BERCOVITZ, Department of Health, City of New York.

Diagnosis of Intestinal Parasites Exhibit includes demonstration of the salt flotation technique of stool examination for ova of the common intestinal parasites; drawings showing the appearance of intestinal parasites accompanied by microscopic stool specimens; diagrams showing fundamental facts of life history of parasites and relation to human pathologic changes; notes on accepted methods of treatment.

L. E. PRICKMAN, Mayo Foundation for Medical Education and Research, Rochester, Minn.

Differential Diagnosis of Asthma Exhibit includes a semi-diagrammatic model of a section through the head and thorax revealing the respiratory passages, lungs and certain adjacent organs showing a number of representative lesions which may produce symptoms that may easily be mistaken for asthma. Transparencies show explanatory notes characteristic roentgenograms, photographs of bronchoscopy and laryngoscopy and an outline of the differential diagnosis of asthma.

IRVING S. WRIGHT, A. W. DURYEE and Co-Workers, Vascular Clinic, New York Post-Graduate Medical School and Hospital, Columbia University, and Second Medical Division, Cornell University, Bellevue Hospital, New York.

Peripheral Vascular System The effects of (a) choline derivatives, (b) non-insulin containing pancreatic tissue extract, (c) ascorbic acid. Exhibit of charts and apparatus

showing comparative effects of several of the choline derivatives and non-insulin containing pancreatic tissue extract from both a physiologic and a therapeutic point of view. The use of ascorbic acid (crystalline vitamin C) in hemorrhagic diseases and its effect on the capillary fragility will be included.

JOHN C. RUDDOCK, Los Angeles

Peritoneoscopy A diagnostic procedure for examining peritoneal cavity and its contents. Exhibit of drawings, photographs, legends and descriptions of cases showing (1) visualization of all abdominal viscera, (2) determination of operability of gastric lesions, (3) evacuation of ascitic fluid, (4) biopsies, (5) demonstration of technique of peritoneoscopy.

ALBERT S. HYMAN, HARRY J. LOWEN, CHARLES HERTZMAN, EMIL KLEIN, J. SANTE DIASIO, MAURICE ZIMMERMAN, Within Foundation for the Study and Prevention of Heart Disease, Beth David Hospital, New York.

Recent Advances in Clinical Cardiology Exhibit of charts, records, models, photographs and original specimens of (1) treatment of decompensation, (2) tests for cardiac reserve, (3) transthoracic electrocardiography, (4) the diving heart, (5) infra-red cardiac photography. Demonstration of the clinical and bedside employment of new studies and methods in the diagnosis and treatment of heart diseases.

VALDE E. ABBOTT, McGill University, Montreal

Clinical Classification of Congenital Cardiac Disease Exhibit of pictures, drawings, paintings, charts, diagrams, roentgenograms and tracings, and anatomic and pathologic specimens showing fish and reptilian hearts and various types of cardiac anomalies. Lantern slide demonstration.

L. G. ROWNTREE, J. H. CLARK and ARTHUR STEINBERG, Philadelphia Institute of Medical Research, Philadelphia General Hospital, Philadelphia, and A. M. HANSON, Faribault, Minn.

The Biological Effects of Thyroid and Pituitary Extracts (Hanson) Exhibit of rats, roentgenograms, photographs, electrocardiograms and motion pictures showing glandular material.

CLAYTON J. LUNDY, Chicago

Motion Pictures (1) Mechanism and Electrocardiographic Registration of the heart in Health and Disease, (2) The Arrhythmias.

Section on Surgery, General and Abdominal

Section exhibit committee: ALTON OCHSNER, chairman, New Orleans; JOHN J. MORTON, JR., Rochester, N. Y., and W. E. GALLIE, Toronto.

In addition to the exhibits listed here, the Section on Surgery, General and Abdominal, is contributing to the Symposium on Cancer.

HUBLEY R. OWEN, Medical Division, Department of Public Safety, Philadelphia.

First Aid in Relation to Patrolmen and Firemen Exhibit of first aid treatment and emergency splinting of fractures as used in the bureaus of police and fire, methods of artificial respiration, treatment of wounds, use of tourniquets, etc., demonstration by members of the bureaus of police and fire, emergency splinting, photographs of methods of first aid taught in the police and fire schools.

FREDERICK A. BOTHE and CARL F. KOENIG, Presbyterian and Stetson hospitals, Philadelphia.

Studies in Hyperthyroidism Exhibit of charts and lantern demonstration showing (a) electrocardiograms before and after thyroidectomy demonstrating disturbances of conductivity with normals for comparison, (b) radiographic demonstration of distortion and compression of the trachea stressing advantage of the lateral view, (c) case reports and follow-up studies of hyperthyroidism in pregnancy, (d) microscopic tissue changes in hyperthyroidism. Roentgenograms demonstrate distortion and compression of the trachea especially in the lateral view.

JOSEPH FELSEN and A. G. OSORSKY, Bronx Hospital, New York.

Pharyngogenic Hematogenous Streptococcal Peritonitis (so-called Primary Peritonitis) Exhibit showing clinical and

pathologic studies, animal studies, epierisis (human and animal work), immunologic studies, correlation of data and pathogenesis. Clinical features of the disease point to throat as primary source of infection. Disease reproduced in healthy rabbits by intravenous injections of strains recovered from peritoneum, blood, spinal fluid etc., of patients. Antigemic studies to establish similarity of strains. Pathologic lesions in human and animal identical. Bacteriologic and histopathologic studies to prove hematogenous, metastatic nature of disease. Infection of peritoneum occurs through focal intestinal lesions.

STUART W. HARRINGTON and WILLIS S. LEMON, Mayo Foundation for Medical Education and Research, Rochester, Minn.

Surgical Treatment and Clinical Manifestations of Various Types of Diaphragmatic Hernia and Intrathoracic Tumors. Experimental studies on the diaphragm of the dog. Exhibit depicts various types of congenital and traumatic hernias by roentgenograms and moulages. Roentgenograms show the herniated viscera on admission and after surgical repair of the hernia. Moulages show the location of the various defects and openings in the diaphragm and the herniated viscera as found at operation. Drawings and moulages show the various stages in the technique of the surgical treatment of repair of the hernias. The exhibit of intrathoracic tumors consists of the anterior and posterior mediastinal growths, as well as intrathoracic tumors of the chest wall that protrude into the thoracic cavity. Roentgenograms of the various types of tumors, both benign and malignant, before and after surgical removal. Moulages and drawings made at the time of operative removal of these growths show their location and the various stages in the technique of their surgical removal. Experimental studies on the diaphragm of the dog include the enervation of the diaphragm, its lymphatic system and the disturbances in function following phrenic anastomosis.

MAX THORPE, American Hospital, Chicago

Electrosurgical Obliteration of the Gallbladder. Exhibit of wax models, transparencies and photomicrographs showing the mechanism of biliary leakage from the unprotected gallbladder bed in classic cholecystectomy. Photomicrographs and drawings depicting the effects of electrocoagulation of the gallbladder bed effectually preventing leakage, chart studies of mortality rates. Wax models of technical details of operation, augmented by motion pictures.

CHARLES S. WHITE and J. LLOYD COLLINS, Department of Surgery, George Washington University School of Medicine, Washington, D. C.

Surgical Anatomy of Total Ablation of the Thyroid Gland. Exhibit of series of illustrations from dissections and operations showing the relative anatomy of the thyroid and parathyroid glands and the recurrent laryngeal nerves.

J. O. BOWER, J. C. BURNS and H. A. K. MENGLE, Philadelphia

Spreading Peritonitis Complicating Acute Perforative Appendicitis. Charts showing incidence and mortality of spreading peritonitis, after administration of laxatives and in the absence of laxatives, natural color photographs of spreading peritonitis in living dogs, both without laxatives and following the administration of laxatives, drawings showing conversion of a localizing into a spreading process, correct and incorrect ways of opening appendiceal abscess, and relocation of incision to prevent induction of a spreading peritonitis, charts showing, by the rate of peritoneal absorption, the effect of anesthetics spreading peritonitis induced by laxatives, photographs showing how peritoneal absorption was studied: (1) use of colloidal graphite injected intraperitoneally, (2) splitting of sternum to expose subternal lymphatics, (3) appearance of graphite in subternal lymphatics. Natural color photographs illustrating the various circulatory and other changes during the different stages of spreading peritonitis.

HAROLD M. TRUSLER, F. G. HEVILICH and J. F. GLORE, Indiana University School of Medicine, Indianapolis

Plastic and Reconstructive Surgery. Exhibit of wax models and photographs showing problems and results of reconstructive

surgery for the relief of burn scar deformities, harelip and cleft palate, malignant growths of the head and neck, and other conditions. Methods are illustrated by diagrammatic color drawings and motion pictures.

HAROLD L. FOSS, George F. Geisinger Memorial Hospital, Danville, Pa.

The Surgical Treatment of Goiter. Exhibit consists of 1. Transparencies, illustrating technique of thyroidectomy with several new features demonstrated. 2. Transparencies of patients suffering from exophthalmic goiter showing their condition before operation and after treatment has been completed. 3. Motion picture amplifying the foregoing problems.

GROUP EXHIBIT, FRANK H. LAHEY and R. B. CATTELL, Lahey Clinic, Boston

A Surgical Treatment of Thyroid Diseases. B. *Exploration of Common Duct*. C. *Abdominoperineal Resection of the Rectum*. Exhibit of illustrations of thyroid operations, results of blood iodine determinations, results of impedance angle determinations in thyroid disease, moulages of thyroid anatomy. Specimens and illustrations of carcinoma of the rectum. Illustrations, moulages and illustrations together with tables of common and hepatic bile duct injuries and stones.

DAVID D. BERLIN, CHARLES G. MYTTER, L. M. FREEDMAN and M. J. SCHLESINGER, Beth Israel Hospital, Boston

Total Thyroidectomy for Chronic Intractable Heart Disease. Exhibit of drawings, diagrams and motion pictures made in the operating room and in the anatomy laboratory illustrating surgical anatomy, technical considerations and end results.

LEWIS M. HURNTHAL and FRANK N. ALLAN, Lahey Clinic, Boston

Clinical Endocrinology. Exhibit showing photographs of patients with definite endocrine disorders with diagnostic data. A three reel motion picture shows the various disorders and results of treatment and the physiology of menstruation.

Section on Obstetrics, Gynecology and Abdominal Surgery

Section exhibit committee: H. C. HESSELTINE, chairman, Chicago, J. R. MILLER, Hartford, Conn., D. P. MURPHY, Philadelphia, and N. W. PHILPOTT, Montreal.

Special features of the Section on Obstetrics, Gynecology and Abdominal Surgery will be an exhibit on Treatment of Obstetric and Gynecologic Hemorrhage and a motion picture program shown in a space adjoining the exhibit. The section is also cooperating in the Symposium on Cancer.

SPECIAL EXHIBIT, SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY

Treatment of Obstetric and Gynecologic Hemorrhage. Exhibit of sketches, drawings, diagrams and pictures showing obstetric complications such as placenta praevia, premature separation of the placenta, lacerations and ruptures of the birth canal and atony of the uterus, together with methods of combating and treating such conditions. Motion pictures in an area adjoining the exhibit will show postpartum hemorrhage, blood transfusions, and so on. Among the special demonstrators for the exhibit will be H. C. Hesselstine, Chicago, J. R. Miller, Hartford, Conn., Douglas P. Murphy, Philadelphia, and N. W. Philpott, Montreal.

CHARLES MAZER and S. LEON ISRAEL, Mount Sinai Hospital, Philadelphia

Clinical and Experimental Studies on Effects of Huge Doses of the Estrus-Inducing Hormones. Exhibit of photomicrographs showing the pituitary and ovarian effects of large doses of estrus-inducing hormone as compared with the effects of small doses, motion pictures depicting the technique of ascertaining the amount of estrus-inducing hormone present in the blood and in the twenty-four hour output of urine as a guide in determining clinically the required dosage. Charts showing the effect of large doses of the product on the menstrual rhythm of normal, amenorrheic and dysmenorrheic women, charts showing the effect of huge doses in the severe menopausal

syndrome, gonorrheal vaginitis, amenorrhea, dysmenorrhea, adenosis of the breast with nipple bleeding and kraurosis vulvae.

AARON E. KANTER, CARL P. BAUER and ARTHUR H. KLA-
WANS, Rush Medical College of the University of Chicago, Chicago

New Biologic Test for Hormones in Pregnancy Urine Exhibit showing the living Japanese bitterling used in the tests and mounted specimens showing the positive and negative reactions together with drawings and charts explanatory of the results obtained and the various applications of the test, reconstruction drawings of the anatomy of the bitterling both gross and microscopic.

F. L. ADAIR and M. EDWARD DAVIS, Department of Obstetrics and Gynecology, University of Chicago, Chicago

Development of Ergot as a Therapeutic Agent Exhibit includes historical background of ergot, depicting the role that the fungus played in the progress of civilization, epidemic manifestations of ergotism, cultivation of the fungus for medicinal use, development of the crude ergot as a therapeutic agent, isolation of the known constituents of ergot and their pharmacologic and therapeutic activity, biologic methods of assay for the determination of the potency and standardization of ergot preparations, new active principle isolated from ergot in its crystalline state, together with its pharmacologic and medicinal properties

KARL JOHN KARNAKY, Department of Gynecology and Obstetrics, John Sealy Hospital, Texas University School of Medicine, Galveston, and Jefferson Davis Hospital, Houston

Causes and Treatment of Leukorrhea, with Special Reference to Trichomonas Vaginalis, Monilia Albicans and Cervical Lesions Exhibit of charts, pictures and diagrams of the causes of leukorrhea, charts showing methods of cauterization of the cervix and end results, methods of diagnosis, morphology and modes of transmission of Trichomonas vaginalis and Monilia albicans. Motion picture is included on Trichomonas vaginalis and Monilia albicans

P. BROOKE BLAND, ARTHUR FIRST and LEOPOLD GOLDSTEIN, Jefferson Medical College, Philadelphia

Clinical Investigation of Functional Sterility Exhibit demonstrating routine procedures and hormone tests employed in determining etiologic factors, estrin and anterior pituitary sex hormone determination of the blood and urine and their diagnostic significance, together with the value of premenstrual curettage.

LOUIS LEHRFELD, Department of Public Health, Philadelphia

Control of Ophthalmia Neonatorum Exhibit of statistical charts and motion pictures pointing out the missing link in the further reduction of ophthalmia neonatorum, namely the treatment of gonorrhea in the expectant mother, the need for change of the present technic of preventive measures in the eyes of the new-born showing that 1 per cent silver nitrate is too irritating and that full reliance should not be placed on a single drop of any germicide, the need for the instillation of 0.5 per cent silver nitrate on three successive days

ROBERT P. BALL, Baroness Erlanger Hospital, Chattanooga, Tenn.

Röntgen Pelvimetry and Fetal Cephalometry Exhibit of roentgenograms, charts and legends showing cases measured before delivery with new technic of pelvimetry and fetal cephalometry presented in detail, utilizing drawings and diagrams

CHARLES A. BEHNEY and DOUGLAS P. MURPHY, Department of Obstetrics and Gynecology, University of Pennsylvania School of Medicine Philadelphia

Carcinoma of the Cervix—Its Early Detection For description see Symposium on Cancer

CHARLES C. NORRIS, FRANCIS S. DUNNE and PENDLETON TOMPKINS, Department of Obstetrics and Gynecology, University of Pennsylvania School of Medicine Philadelphia

Carcinoma of the Cervix—An Analytic Study For description see Symposium on Cancer

Section on Ophthalmology

Section exhibit committee GEORGIANA D'VORAK-THEOBALD, chairman, Oak Park, WILFRED E. FRY, Philadelphia, PARKER HEATH, Detroit, and ALEXANDER E. MACDONALD, Toronto

The Section on Ophthalmology will conduct a motion picture program in a space adjoining the exhibits

CONRAD BERENS and BRITAIN F. PAYNE, Lighthouse Eye Clinic, New York

Certain Phases in the Development of the Human Eye Exhibit of series of photomicrographs of the eyes of human embryos

DEWEY KATZ and ALFRED C. LEDOUX, University of Chicago, Chicago

Measurement (Roentgenometry) of Anteroposterior Diameter of Eyeball in Situ Correlated with Micrometer Measurement Following Enucleation Exhibit of roentgenograms in which the apex of the cornea and the external surface of the posterior half of the eyeball are outlined by use of opaque mediums used in an original manner. Roentgen triangulation measurements in situ have been correlated with micrometer measurements of the eye following enucleation. The exhibit will illustrate the technic used and will show the roentgenograms of the eyeballs in the orbits

MANUEL URIBE TRONCOSO and RAMON CASTROVIEJO, Institute of Ophthalmology, Columbia University, New York

Comparative Anatomy of the Angle of the Anterior Chamber in Mammals Exhibit showing new method of micro-anatomy of the eye with slit lamp microscope, showing the organs from in front with large magnifications and a beautiful view of the structures, frontal observation supplemented by a side view of the sections and easy correlation of both aspects, studies in herbivora, carnivora, monkeys and man first in the living eye with the gonioscope and then in prepared sections of enucleated eyes

ALBERT D. RUEDEMANN and V. SEITZ, Cleveland Clinic, Cleveland

Conjunctival Vessel Photography Apparatus, camera and light. Exhibit showing a camera and technic of photographing the conjunctival capillaries, similar to that for the fingernail bed or skin, photographs of lesions at the limbus

THOMAS D. ALLEN and G. W. NETHERCUT, Illinois Eye and Ear Infirmary, Chicago

First Aid in Eye Injuries Exhibit of models, charts and photographs showing first aid in eye injuries with which the physician in general practice should be acquainted

A. HOWARD PIRIE, Royal Victoria Hospital, Montreal

Reading and Seeing Pictures with Eyes Closed Demonstration of apparatus allowing spectators to read and see pictures with eyes closed

EDMUND B. SPAETH, Philadelphia

Ophthalmic Plastic Surgery Exhibit showing a series of charts to illustrate cases of ophthalmic plastic surgery before and after correction

FRANCIS HEED ADLER, GEORGE E. BERNER and GEORGE P. MEYER, Department of Physiology, University of Pennsylvania, Philadelphia

Testing of Tonometers Exhibit showing instrument by which the accuracy of tonometers can be tested

EMANUEL KRIMSKI, Brooklyn

New Precision Type of Stereoscope Exhibit of stereoscope which enables the examiner to determine at a glance the amount of convergence or divergence with variable accommodations to fuse split pictures by incorporating (a) viewing lenses of selective length and for variable pupillary separation, (b) movable calibrated rod, (c) viewer calibrated to record the amount of separation of split images, (d) table to which examiner may refer so as to determine readily vergence readings

Motion Pictures

JOHN OLIVER McREYNOLDS, Dallas, Texas 'Operations on the Eye'

Section on Laryngology, Otology and Rhinology

Section exhibit committee WILLIAM V. MURPHY,* chairman, Cleveland, AUSTIN A. HAYDEN, Chicago JOHN J. SIEFA, Memphis, and GREGOR MCGREGOR, Toronto

In addition to its section exhibit, the Section on Laryngology, Otology and Rhinology is contributing to the Symposium on Cancer

JAMES HAROLD MENDEL Philadelphia

Lar Drums and Their Interpretation Exhibit of a series of original plaster models illustrating in correct colors the progressive stages of acute otitis media the normal drum and progressive course of acute ear infection up to the point at which myringotomy is indicated various types of bulging and the treatment are shown Contrasted to these are models of other bulgings the treatment of which is entirely different Rare types are included in the collection some of which must be carefully differentiated from the normal

F. H. SHANNON, St. Michael's Hospital Toronto

Accessory Nasal Sinuses Exhibit of roentgenograms showing accessory nasal sinuses

RAPHAEL SCHILLINGER Brooklyn

Chronic Nasal Sinusitis Exhibit of roentgenograms of nasal sinuses for the purpose of comparing diagnostic value of (a) simple standard roentgen examination (b) an examination with the aid of radiopaques, paying particular attention to a study of the time element necessary for evacuation of the opaque from the sinus whereby an index of physiologic activity of the sinus mucosa is established clinical and operative data and microscopic pathologic changes will be shown

SAMUEL J. KOPETZKY, RAIPH ALMOHR and HENRI K. TAYLOR Beth Israel Hospital New York

Diagnostic and Surgical Aspect of Suppuration of the Pneumatic Petrous Bone Exhibit consists of (1) tribulations of symptoms and clinical course (2) models and temporal bones showing types of operative approach (3) charts of cases (4) roentgenograms showing types of lesions, stages in diagnosis and postoperative condition and healing

L. H. CLERF, B. L. CRAWFORD and R. M. LUKENS, Jefferson Hospital Philadelphia

Neoplasms of the Larynx For description see Symposium on Cancer

AMERICAN FEDERATION OF ORGANIZATION FOR THE HARD OF HEARING, INC. Washington, D. C. For description see Educational Classification

COMMITTEE ON DEAFNESS PREVENTION AND AMELIORATION, AMERICAN ACADEMY OF OPHTHALMOLOGY AND OTOLARYNGOLOGY

Deafness Prevention and Amelioration For description see Educational Classification

Section on Pediatrics

Section exhibit committee F. THOMAS MITCHELL chairman Memphis, Tenn., ABRAHAM LEVINSON, Chicago WALTER B. STEWART, Atlantic City, and ALLAN BROWN, Toronto

One of the features of the exhibit of the Section on Pediatrics is the Symposium on Acute Infections of the Central Nervous System in Children The section is also contributing to the Symposium on Tuberculosis being conducted by the Section on Preventive and Industrial Medicine and Public Health

ALLAN ROY DAFOE, Callander, Ontario, and WILLIAM A. DAFOE, Toronto

Chart Life of the Dionne Quintuplets Exhibit showing weight graphs of five babies for ten months, combined chart showing daily weight of all for first month together with individual charts of daily weight of each, chart of caloric intake for first five months for smallest and largest babies, table showing exact feedings, manner and frequency of feeding, short summary of background and certain incidents in the lives of the babies photographs map showing location of Callander

GIRNVILLE GIDDINGS, Atlanta, Ga

Observations on Normal Children Exhibit showing observations made on normal children, including regular and periodic urinalyses, blood counts, blood pressure readings, height and weight curves, electrocardiogram and basal metabolism tests, further observations on sleep

G. ALLEN ROBINSON and R. FRANKLIN CARTER, New York

Surface Tumors in Childhood Exhibit showing the various types of benign and malignant tumors occurring in children, differential diagnosis, best methods of treatment, and end results obtained in a large series of cases

LIFE BIVINGS, Emory University School of Medicine, Atlanta

Feet in Infancy and Childhood Foot Printing and Classification of Foot Prints Comparison of the Feet of White and Negroes Exhibit of plaster casts of feet of infants and children, normal and abnormal, white and Negroes, demonstration of new device for recording walking foot prints and heel prints without soiling the feet or heels foot print records of various types of feet and photographs of various types of feet

T. G. H. DRAKE, Hospital for Sick Children, Toronto

Infant Care and Feeding in Ancient Times An exhibit of antiquities consisting of (a) Egyptian, Roman Greek amulets, from 300 B. C. to 300 A. D. to promote easy labor, increase lactation and protect the child from various diseases and the 'evil eye' (b) English and French documents, prints and medals from 1660 to 1820 concerning foundlings and wetnursing, (c) infants' feeding utensils, from 300 B. C. to 1850 A. D.

CHARLES F. CHURCH and DOROTHY V. WHIPPLE, University of Pennsylvania School of Medicine, Philadelphia

Vitamin B and Fat in Metabolism Exhibit shows experimental beriberi and experimental fat deficiency diseases and their signs and symptoms, correlated with functional tests and pathologic observations, the interrelation of the physiologic requirements of the organism for fat and for vitamin B and the failure of rancid fat to meet lipid requirements, ease with which cod liver oil undergoes oxidative rancidity and how deterioration of cod liver oil is a frequent and clinically important source of rancid fat in the dietary of children.

S. A. WEISMAN, University of Minnesota Medical School, Minneapolis

Normal Development of the Human Chest For description see Symposium on Tuberculosis

ISAAC ERB and GLADYS L. BOYD, Hospital for Sick Children, University of Toronto Department of Pediatrics, Toronto

Childhood Pulmonary Tuberculosis and Bronchiectasis For description see Symposium on Tuberculosis

SYMPOSIUM ON ACUTE INFECTIONS OF THE CENTRAL NERVOUS SYSTEM IN CHILDHOOD

GREGORY SHWARTZMAN, Mount Sinai Hospital, New York

Local Skin Reactivity in Studies on Meningococcal Meningitis, Tuberculosis, and Malignant Tumors Exhibit dealing with (1) highly toxic factors derived from meningococcus as demonstrated by the phenomenon. (2) Hitherto unknown antitoxins as demonstrated by the phenomenon. (3) The methods of preparation of these antitoxins in horses. (4) The relation of these antitoxins to agglutinins. (5) Demonstration of the auxiliary antibodies necessary for the neutralization of the meningococcus toxins. (6) Demonstration of certain reactivating factors inhibitory to toxin and antitoxin neutralizations. (7) New toxic substances in Bacillus tuberculosis demonstrated by means of the phenomenon. (8) The relationship of these toxic substances to problems of tuberculin hypersensitivity. (9) The role of Bacillus tuberculosis toxic substances in tuberculous lesions. (10) Failures of growth, regressions and hemorrhagic lesions of malignant tumors elicited by certain bacterial factors

JOSEPHINE B. NEAL, Bureau of Laboratories, Department of Health, New York

Meningitis Exhibit of charts and tables showing distribution of meningitis by age and etiology also salient points in diagnosis and treatment

MAURICE BRODIE, Bureau of Laboratories, Department of Health and Department of Bacteriology, New York University and Bellevue Medical School, New York

Poliomyelitis Vaccine Exhibit shows preparation of the vaccine and the results obtained with it in children and in experimental animals, results of its use in an epidemic area in California and its application for the protection of the community in an endemic focus. Neutralization test with mice for determination of susceptibility to poliomyelitis

SIDNEY D. KRAMER, Long Island College of Medicine, Brooklyn

Poliomyelitis Exhibit of charts and photographs on epidemiology, immunity symptomatology and preparalytic diagnosis, illustrating various evidence on which concept of the disease is based. Evidence shows it is no longer a mysterious disease and the experimental and other evidence bring out a striking analogy to better known diseases, particularly diphtheria. The presence of healthy carriers explains adequately the extensive immunity to so rare a disease. Poliomyelitis is a well defined and recognizable clinical entity

ABRAHAM LEVINSON and DAVID J. COHN, Michael Reese Hospital, Chicago

Studies in Cerebrospinal Fluid Exhibit shows comparative studies of lumbar and cistern fluids in various conditions and demonstration of simple quantitative method of determining dextrose in cerebrospinal fluid

GEORGE M. RETAN, Syracuse University College of Medicine, Syracuse, N. Y.

Forced Pervascular Drainage for the Treatment of Infections of the Central Nervous System Exhibit of charts illustrating various phases of treatment case histories, and photomicrographs of sections of the central nervous system continuous motion picture demonstration featuring the treatment of poliomyelitis, acute encephalitis and chorea

Section on Pharmacology and Therapeutics

Section exhibit committee C. D. LEAKE, chairman, San Francisco, C. F. SCHMIDT, Philadelphia, and V. E. HENDERSON, Toronto

E. PERRY McCULLAGH, W. KENNETH CUYLER and D. ROY McCULLAGH, Cleveland Clinic Foundation, Cleveland

Experimental and Clinical Studies of Hormone Assays Exhibit of charts, transilluminated slides, models and assay apparatus showing the gonadotropic hormones of the pituitary thyroid hormone testicular hormone and estrogenic hormone, methods of assay for these hormones, applicable for clinical use, methods of assay for gonadotropic hormone by means of the Friedman test measurement of the thyroid hormone by blood iodine determination in human beings, methods of assay for testicular and ovarian hormones in the urine. The clinical significance of the assays will be indicated

GROVER C. PENBERTH and CHARLES N. WELLER, Children's Hospital of Michigan, Detroit

Treatment of Burns with Tannic Acid Exhibit of photographs representing the various degrees of burns and stages during treatment, motion picture depicting the use of tannic acid and subsequent procedures in the treatment of burns

SANFORD M. ROSENTHAL, National Institute of Health, Washington, D. C.

Formaldehyde Sulphoxylate as an Antidote for Acute Mercury Poisoning Exhibit of charts showing blood nonprotein nitrogen in control (corrosive mercuric chloride) and treated animals microscopic and gross appearance of kidneys of treated and untreated animals clinical results, reducing power of the drug as demonstrated with oxidation reduction indicators reducing power of the blood serum after injections of the drug chemical action of the drug on mercuric chloride color tests for the drug

WILLIAM BIERMAN, Beth Israel Hospital, New York

Skin Surface Temperatures in the Diagnosis and Treatment of Peripheral Vascular Diseases Exhibit of charts showing determinations in the normal and in pathologic states—arteriosclerosis, thrombo-angitis obliterans varicose veins, embolism

relation between skin surface temperature of the toe and other parts of the body, changes during fever induced by intravenous typhoid and physical measures, effect on toe temperature of heat and cold applied directly and remotely, temperature of the toe as influenced by intravenous salt solution, positive and negative pressure, thermostatically controlled heat, nerve block (spinal and general anesthesia), acetylsalicylic acid, hot water, tea, coffee alcohol and smoking

CARL E. ERVIN, HENRY F. HUNT and WILLIAM H. DEARING, George F. Geisinger Memorial Hospital, Danville, Pa.

Diseases of the Kidney Exhibit of wax models and enlarged photomicrographic transparencies of the gross and microscopic structure of the kidney. Charts show the present concepts of the etiology of nephritis with an outline of the modern methods of treatment. Other forms of kidney infections such as those produced by the staphylococcus and B. tuberculosis demonstrated by models and photomicrographs. Exhibit emphasizes the fact that most kidney lesions are merely expressions of disease elsewhere in the body

M. S. DOOLEY and J. SOLON MORDELL, University Hospital and College of Medicine, Syracuse University, Syracuse, N. Y.

Rational Drug Therapy in Hospitals Exhibit of photographs placards, lantern slides, standard containers rules governing drug orders, and so on, showing how a limited scope of approved standard drugs is controlled without encroachments in a general open staff hospital

Section on Pathology and Physiology

Section exhibit committee FRANK W. HARTMAN, chairman, Detroit, A. B. LUCKHARDT, Chicago, E. P. LYON, Minneapolis, J. P. SIMONDS, Chicago, and WILLIAM BOYD, Winnipeg

In addition to the exhibits described here, the Section on Pathology and Physiology is participating in the Symposium on Cancer

WILLIAM C. LANGSTON and PAUL L. DAY, University of Arkansas School of Medicine, Little Rock

Leukopenia, Anemia and Associated Manifestations of Vitamin Deficiency in the Monkey Exhibit of tables charts and photographs illustrating the effect of the withdrawal of vitamin G from the diet of the monkey, including diet used, weight curves, survival periods, oral lesions and other clinical signs, and progressive changes seen in hemoglobin values, total red cell counts, total white cell counts, differential white cell counts, reticulocytes, platelets cell volume, clotting time and blood chemical changes. Stained blood preparations, with microscopes for examination will be available.

EARL W. FLOSDORF and STUART MUDD, University of Pennsylvania School of Medicine, Philadelphia

Preservation of Serum and Other Biologicals by Desiccation in Vacuo from the Frozen State Exhibit will consist of apparatus and samples of normal human adult serum, convalescent human and immune animal serums, serum proteins, breast milk, and the like processed on this apparatus

ISAAC SCHOUR and A. G. BRODIE, University of Illinois College of Dentistry, Chicago

Effect of Metabolic Disturbances on Teeth Exhibit of photomicrographs, charts and roentgenograms showing (1) the effects of hypophysectomy on the incisor and molar of the white rat, retarded eruption smaller size, histopathologic changes and disturbed calcifications, (2) dental changes in a boy suffering from hypopituitarism, which are similar to the experimental observations, (3) effect of experimental hyperparathyroidism on the incisor of the rat, primary reaction of hypocalcified dentin and secondary reaction of hypercalcified dentin, (4) effect of acute fluorosis on enamel and dentin of rat, a disturbed layer for each injection and abnormal change in enamel forming cells within one hour following a single injection

L. W. DIGGS, University of Tennessee, Memphis

Sickle Cell Anemia Exhibit of photographs, photomicrographs drawings and charts giving clinical and pathologic picture of sickle cell anemia, methods used in diagnosis, printed matter summarizing the essential features of the disease, his-

tory, physical observations, blood picture, pathology, differential diagnosis, series of roentgenograms showing bone changes

LAWRENCE J. RILEY and HORTENSE DOUGLAS, Department of Pathology, Montreal General Hospital, Montreal

Pathologic Lesions of the Gastro-Intestinal Tract Exhibit of wax moulages illustrating lesions of the gastro-intestinal tract with a brief summary of the clinical aspects of the patients from whom the specimens were obtained

JULIUS S. WEINGART and ROBERT A. SAGE, Iowa Methodist Hospital, Des Moines, Iowa

Stereoscopic Photographs of Pathologic Specimens Exhibit showing the method of making photographs by a camera designed for the purpose, also the method of development and printing photographs and very fine viewers will demonstrate the superiority of this type of picture over the ordinary one, in illusion of depth, clearness of anatomic arrangements and fine detail of the lesions

DAVID I. ABRAHAMSON and SYDNEY MARCOLIN, Long Island College of Medicine, Brooklyn

Gross and Microscopic Anatomy of the Conduction System in the Mammalian Heart Exhibit of sheep and beef hearts in which the sheath spaces surrounding the individual fibers of the conduction system have been filled with India ink in order to bring the fibers to view, photographs of the fibers in gross specimens and microscopic sections in the dog, pig, sheep and beef hearts. Special emphasis has been placed on the presence of a myocardial Purkinje system which ramifies through the muscle substances of the outer ventricular walls and interventricular septum in all the foregoing hearts

JANE SANDS RONN, J. G. FRED HISS and R. C. RONN, Syracuse University School of Medicine, Syracuse, N. Y.

Cardiac Muscle-Bundle Physiology (experimental coronary lesions) Exhibit shows (1) dissections of injected human hearts, showing the coronary blood supply to specific muscle bundles, (2) experimental anatomic and electrocardiographic evidence delimiting the pathways of conduction in the ventricle of the dog and monkey, (3) typical electrocardiograms of premature beats excited in the superficial ventricular muscles of the dog

MAX STRUMIA, Bryn Mawr Hospital, Bryn Mawr, Pa.

Hematologic Tables, with a New Staining Method for Blood Smears Exhibit of lithographic tables in full colors illustrating all types of human blood cells and all the commonest and most important blood pictures (anemia, leukemias, infections), explanatory notes and staining technique, lantern slides and blood smears demonstrated at the microscope

WILLIAM A. GROOT and STELLA M. ZIMMER, Syracuse University College of Medicine, Syracuse, N. Y.

Leukemia Blood Pictures Exhibit shows various types of leukemia illustrated by photomicrographs of stained blood, colored enlargements and direct color photomicrographs as transparencies. Emphasis is placed on the similarities between the leukemias and the sarcomas, and cytologic evidence thereof is presented. Complete series of the stages of mitotic division from several types of leukemia are included. Haploid mitotic figures in leukemia cells are shown

MILTON B. COHEN, B. S. KLINE and A. M. YOUNG, Asthma and Hay Fever Clinic and Mount Sinai Hospital, Cleveland

Clinical Diagnosis of Periarthritis Nodosa Exhibit of charts, specimens and photographs showing the pathology of periarthritis nodosa, demonstrating the allergic nature of the disease, clinical types and the salient points of diagnosis

FRANK W. HARTMAN, R. D. MCCLURE and C. I. ALLEN, Henry Ford Hospital, Detroit

Further Studies on the Pathology and Treatment of Burns Exhibit of work concerned with the pathologic physiology produced by burns, particularly the shock that follows the burn and later untoward reactions that have been ascribed both to absorption of dead tissue and to infection. Bacteriology of the burned areas is studied in conjunction with various types of treatment, i. e., caron oil, trimetaphenol and tannic acid. Pathologic studies include the histology of the burned areas in various

stages of healing and also of the various regions in association with the acute shock. Treatment is presented in the form of actually burned areas in various stages preserved in natural colors. Various types of treatment are presented in this way for comparison

M. SPIEGEL-ADOLF and E. A. SPIEGEL, Temple University School of Medicine, Philadelphia

Apparatus for Measurement of Polarization and Permeability of Tissues Exhibit of apparatus consisting of a conductance measurement outfit equipped with an oscillator that gives alternating currents of various frequencies (from 560 to 6,800 cycles). It is shown that a difference in conductivity at high and low frequencies is found in tissues or in the presence of certain semipermeable membranes. This difference can be used as measure of polarization and consequently of permeability. The method permits a study of the permeability of tissues *in vivo* in various physiologic and pathologic conditions. This is illustrated by charts

JOHN A. KOLMER, Research Institute of Cutaneous Medicine and Temple University, Philadelphia

Immunity and Infection in Infantile Paralysis Exhibit of charts on susceptibility and immunity, the vaccine, results of immunization, etc.

JESSE G. M. BUILDOWA, Littauer Pneumonia Research Fund of New York University, Harlem Hospital Station, New York

Management of the Pneumonias—Serum Treatment and Oxygen Demonstration of Neufeld and Sabin typing and slide agglutination for the control of dosage. Blood culture technique. Lung suction. Charts showing the reliability of sputum typing. Charts showing the occurrence and importance of bacteremia. Distribution of types. Results of serum treatment in Types I, II, VII, VIII, XIV and XVIII. Motion picture "Management of the Pneumonias"

RAYMOND S. ROSEDALE and DONALD S. MCKAY, Buffalo City Hospital, Buffalo

Primary Lung Cancer—Clinical, Pathologic and Roentgenologic Study For description see Symposium on Cancer

Section on Nervous and Mental Diseases

Section exhibit committee: GROVES B. SMITH, chairman, Godfrey, Ill.; THOMAS J. HELDT, Detroit; LLOYD H. ZIEGLER, Albany; and C. B. FARRAR, Toronto

The Section on Nervous and Mental Diseases will present a special exhibit on the relationship of psychiatry to the physician in general practice. A motion picture program will also be shown in an area adjoining the exhibit.

SPECIAL EXHIBIT, SECTION ON NERVOUS AND MENTAL DISEASES

Relation of Psychiatry to the Physician in General Practice Exhibit of charts, posters, photographs and specimens showing (a) the incidence of mental disease and its economic relationship, as well as the facilities that exist for the care and treatment relative to the general practitioner, (b) clinical evaluations of various aspects of neuropsychiatry and its divisions, including behavior and emotional disturbances, mental deficiency, the psychoneuroses, psychoses and organic conditions that the general practitioner commonly meets, (c) practical applications of everyday treatment aspects. The exhibit will be demonstrated continuously throughout the week by Thomas J. Heldt, Detroit; Lloyd Ziegler, Albany, N. Y.; and Groves B. Smith, Godfrey, Ill.

HERBERT H. SCHOENFELD, CLAUDE MOORE and WALTER FREEMAN, George Washington University, Washington, D. C.
Ventriculography with Thorium Dioxide Exhibit of roentgenograms and transparencies of cases following trephine and the injection of small quantities of colloidal thorium dioxide.

J. A. HANNAH, Ontario Department of Health, Neuropathological and Research Division, Department of Neuropathology, Banting Institute, University of Toronto, Toronto

Microscopic Sections of Whole Brains Showing Various Pathologic Lesions Exhibit of microscopic sections of whole brains cut in various planes, showing the pathologic processes and the common meeting grounds of psychiatry in general medicine

cine, smaller sections of brain and sections of other organs are included to show lesions commonly found in the psychotic as well as the nonpsychotic patient

C M HINCKS, Canadian National Committee for Mental Hygiene, Toronto

Mental Hygiene Progress in Canada Exhibit of charts illustrating in a series of graphs and curves the progress in mental hygiene in Canada

EARL D BOND, EDWARD A STRECKER and Staff, Pennsylvania Hospital, Philadelphia

Mental Hygiene in the Community Exhibit of photomicrographs, charts, diagrams, sketches and apparatus showing types of patients, follow-up studies, recovery rates and behavior reactions of inpatients and outpatients in mental hospitals, diagram of teaching courses in psychiatry and relationship to the psychiatric hospital, motion pictures

GROUP EXHIBIT TEMPLE FAI, W A CHAMBERLAIN J O ARNOLD, JOHN ROYAL MOORE, J GARRETT HICKEY, NICHOLAS GOTTEN and JOHN H TAEFFNER, Temple University School of Medicine, Philadelphia

Correlation of Clinical Results Obtained in Various Branches of Medicine by Regulation of the Cerebral Hydrodynamics and the Methods of Treatment Involved Apparatus demonstrating cerebral volume relationships, showing continuous mechanical alterations of volume occurring within the craniovertebral cavity. Illuminated charts and statistical tables showing a definite decrease in mortality, resulting from treatment directed toward the correction of the disturbances manifested in the fundamental physiology and physical laws concerned with cerebral circulation. The exhibit will include (1) neurosurgical aspects (comparative mortality covering a period of eleven years), (2) obstetric aspects (comparative mortality covering a period of five years), (3) orthopedic aspects (effect on spasticity, observations covering a period of six years), (4) roentgenographic aspects (encephalographic determinations and interpretation), (5) convulsive state and mental retardation (comparative statistics covering a period of eight years), (6) cerebral trauma (statistics of comparative mortalities during a period of eleven years)

FRANCIS C. GRANT, Hospital of the University of Pennsylvania and Graduate Hospital, Philadelphia

Clinical Symptoms and Methods of Diagnosis in Tumors of the Spinal Cord Exhibit showing a series of verified spinal cord tumors illustrating manner of onset and clinical picture accompanying these lesions, the more exact methods of diagnosis by the use of the Queckenstedt test, chloroformed rapeseed oil injection into the subarachnoid space, temperature and skin studies, operative methods illustrated by motion pictures photomicrographs showing the different pathologic types of spinal cord tumor

CHARLES DAVISON, Montefiore Hospital, New York

Neuropathologic Demonstration Complete coronal horizontal and sagittal sections of the brain embedded in celloidin cut 50 microns thick, stained by the myelin sheath and cresyl violet methods, illustrating vascular, neoplastic, infectious toxic and degenerative diseases of the nervous system

CARL P WAGNER and AGNES MEYER, Neuro Psychiatric Institute of the Hartford Retreat, Hartford Conn

Demonstration of Educational Methods to Replace Occupational Therapy Exhibit shows the superiority of educational methods over the traditional type of occupational therapy in training the psychiatric patient. Motion picture in colors will show the technique of introducing class work and developing interest in a diversified curriculum

Motion Pictures Motion pictures will be shown in an area adjoining the exhibit on a schedule to be announced later

Section on Dermatology and Syphilology

Section exhibit committee FRED D WEIDMAN, chairman Philadelphia, CLARK W FINNERUD Chicago ROBERT L GILMAN, Philadelphia, WILLIAM O ROOP Atlantic City and J F BURGESS, Montreal

A feature of the Section on Dermatology and Syphilology is a symposium on syphilis in addition to various other exhibits, many of which illustrate papers read before the section

GEORGE M LEWIS and MARY E. HOPPER, New York Skin and Cancer Unit, New York Post-Graduate Hospital, Columbia University, New York

Differentiation of Fungous Species by Fluorescences Many species of fungi exhibit characteristic fluorescent colorizations when viewed under the "Wood" light. Young primary colonies exhibit the most vivid colors. The hues of young subcultured growths, while of the same character, are not so brilliant. The procedure is a practical aid in the differentiation of fungous species. In scalp ringworm, where the treatment may vary with the causal fungus this method offers a simplified means of distinguishing between the two commonest organisms, namely, *Microsporon Audouinii* and *Microsporon lanosum*

JOHN G DOWNING and S M COUSINS, Boston City Hospital and Harvard School of Biology, Boston

Fungi Pathogenic to Man Exhibit of fungi intended for the instruction of general practitioners or those unfamiliar with mycology. It also includes the results of recent work on significant variations in these fungi

M H GOODMAN with collaboration of L W KETRON, Johns Hopkins Hospital, Baltimore

Various Stages in the Histopathology of Granuloma Annulare Exhibit of slides to illustrate the essential microscopic changes in granuloma annulare, demonstrating gradations from mild changes in the connective tissue to the typical outspoken necrosis found in granuloma annulare.

RHODA W BENHAM, College of Physicians and Surgeons, Columbia University, New York

Pathogenic Fungi—Types of Fungi and the Diseases Which They Cause Exhibit of photographs, cultures and microscopic slides showing cultures of the main groups of pathogenic fungi with pictures of lesions from which they were isolated, also some saprophytes where necessary to bring out differential points. The exhibit includes (1) dermatophytes, (2) cryptococci and *Monilia*, (3) *Coccidioides*, *Blastomyces* and related fungi, (4) *Actinomyces*. Emphasis will be given to classification and criteria for identification

SAMUEL AYRES JR. and N P ANDERSON, Los Angeles

Focal Infection in Dermatology Exhibit of photographs and charts illustrating the role of focal infection in the production of skin lesions, the relation of focal infection to allergy and immunity, the important sources of focal infection, their bacteriology and methods of treatment

S WILLIAM BECKER, Section on Dermatology, University of Chicago, Chicago

Pigmentations of the Skin Exhibit of photographs of clinical cases, microscopic drawings, photomicrographs and charts outlining fundamental principles of normal and pathologic pigmentation.

THEODORE CORNBLEET and E. R. PACE, University of Illinois College of Medicine, Chicago

Sweat Physiologic and Biologic Studies, with Clinical Implications Analyses of sweat from normal persons and those with certain skin disorders will be compared and the difference shown. The results will be used to explain the etiology of some dermatoses. A demonstration will be made to illustrate how profuse sweating changes the skin surface milieu. Exhibit of sweat as a medium for the growth of certain fungi. An exposition will be made of how the sweat as a reducing agent conditions the skin surface

SYMPOSIUM ON SYPHILIS

CLARK W FINNERUD and FRED D WEIDMAN, Chicago and Philadelphia

Cutaneous Manifestations of Syphilis Exhibit of photographs illustrating practically all of the cutaneous manifestations of syphilis

COMMITTEE ON EVALUATION OF SERODIAGNOSTIC TESTS FOR SYPHILIS, American Society of Clinical Pathologists and United States Public Health Service

Evaluation of Serodiagnostic Tests for Syphilis in the United States Exhibit showing the conclusions of the committee upon

sored by the United States Public Health Service and the American Society of Clinical Pathologists

NORMAN TORIAS, St. Louis

Extragenital Chancres Exhibit of photographs of extragenital chancres of the skin and mucous membranes, showing some of the common locations of extragenital chancres and the different forms in which they present themselves, especially of the upper and lower lips

A. H. PARMATTE and LOUIS J. HAMPTON Rush Medical College and Cook County Hospital Chicago

Diagnosis of Congenital Syphilis Exhibit of statistical charts and graphs showing the results of clinical, serologic and roentgenologic examinations on a series of infants of syphilitic mothers at various periods during the first year of life, also roentgenograms showing types of osseous lesions produced by congenital syphilis

CLAUDE L. CUMMER and CHARLES G. IAROCO Department of Dermatology Charity Hospital Cleveland

Skin Manifestations of Syphilis Exhibit of a collection of transparent positive prints demonstrating the cardinal points in the recognition of primary, secondary, tertiary and hereditary syphilis

JOSEPH A. KLAUDER and THOMAS BUTTERWORTH Philadelphia

Syphilis from Blood Transfusion Exhibit of a chart showing syphilis from blood transfusion

C. F. LEHMANN and J. L. PIPKIN San Antonio Texas

Hypertrophic Type of Coccidioidal Granuloma Exhibit of photographs photomicrographs roentgenograms cultures and mouldages showing the clinical picture before and after treatment tissue organism and culture

DAVID R. MORGAN Department of Dermatology and Museum Jefferson Medical College Philadelphia

Morbid Anatomy of Syphilis Exhibit of specimens plate preparations bones and wax models of skin lesions showing the morbid anatomy of syphilis especially vascular syphilis and syphilis of the bones and viscera

S. S. GREENBAUM and DAVID MERANZF Mount Sinai Hospital Philadelphia

Laboratory Aspects of Syphilis Exhibit showing experimental rabbit syphilis darkfield exhibit of *Spirochaeta pallida* stained specimens of darkfield *Spirochaeta pallida* demonstrations of Wassermann Kluver and Kahn blood tests colloidal gold test on spinal fluid

DUDLEY C. SMITH W. A. BRUMFIELD JR. and E. E. BARNSDALE University of Virginia Charlottesville, Va.

Practical Epidemiology of Syphilis Exhibit of charts illustrating the efficacy of tracing exposures of syphilis and the use of population group surveys in locating syphilitic infections

Section on Preventive and Industrial Medicine and Public Health

Section exhibit committee PAUL A. DAVIS, chairman, Akron Ohio, ALICE HAMILTON, Boston, THURMAN B. RICE, Indianapolis, and H. G. GRANT, Halifax

The Section on Preventive and Industrial Medicine and Public Health presents as a special feature an exhibit symposium on the subject of tuberculosis devoted especially to those aspects of the disease of interest to the physician in general practice

W. G. SMILLIE and W. S. WEILS Harvard School of Public Health, Boston

Air-Borne Infection Exhibit shows apparatus for testing air and charts illustrating results of tests, small portable machine for pollen determination, with illustrative material

D. A. IRWIN Department of Medical Research, University of Toronto, Toronto

Experimental Silicosis Exhibit of a series of photomicrographs illustrating the lesions of experimental silicosis

THURMAN B. RICE and JAMES R. REEVES Indiana University School of Medicine Indianapolis

Etiology of Anaerobic Infections Exhibit shows nature of gas gangrene infections and criticism of current methods of

bacteriologic diagnosis, methods of culturing with anaerobic technique, types of patients more likely to have gas gangrene infection anaerobic organisms cultured from presumably normal tissue (animal and human), undescribed species of anaerobic bacteria *Clostridium* with two spores

M. B. BRAIDEN MAURICE LENARSKY L. W. SMITH and C. A. GIFFNEY Willard Parker Hospital, New York

Rapid Method for the Culture of Diphtheria Bacilli Exhibit of (1) photomicrographs from stained smears from four hour (rapid method) cultures taken from diphtheria membranes (2) photomicrographs of stained smears from rapid method transplants for obtaining pure culture for virulence tests in carriers (3) charts to show comparative results of rapid method and Loeffler method in diphtheria cases and controls, (4) charts to show higher percentage of identification of virulent carriers by the new method (5) culture tubes for new rapid method.

LOUIS SCHWARTZ United States Public Health Service, Washington D. C.

Industrial Dermatoses Exhibit of charts showing causes pictures of cases, mouldages of cases, samples of articles and chemicals causing industrial dermatoses

K. K. CHIFF CHARLES L. ROSE and G. H. A. CLOWES Lilly Research Laboratories Indianapolis

Cyanide Poisoning Exhibit showing sources of cyanide poisoning death rates in registration area and large cities, crucial tests for diagnosis antidotes previously advocated and their failures modern method of treatment

WALTER S. CORNELL, Division of School Medical Inspection, Board of Education and Department of Public Health, Philadelphia

School Medical Inspection Exhibit of statistical tables, charts and photographs showing medical examination of pupils, health status correction of diseases and defects proportion of diseases and defects treated by private physicians and public clinics respectively reasons for non treatment condition of health of pupil population special classes for partly sighted, deaf crippled sanitary standards used in inspecting school buildings Special investigation of field of school child health roentgen examinations of chests, later roentgen examinations to ascertain progress of tuberculous infection audiometer tests of hearing later tests to determine permanence of defective hearing nutritional survey before and during current economic depression school factors in transmission of scarlet fever, periodic health examinations for teachers

SYMPOSIUM ON TUBERCULOSIS

CHICAGO MUNICIPAL TUBERCULOSIS SANITARIUM Allan J. Hrubn Chicago

Demonstration of Collapse Therapy in Pulmonary Tuberculosis Exhibit of roentgenograms of the chest before and after collapse therapy by various methods, pneumothorax, intra pleural pneumolysis, phrenico-cyesis and thoracoplasty surgical technique shown by a motion picture, demonstration of relative results in collapse therapy

S. A. WEISMAN University of Minnesota Medical School Minneapolis

Normal Development of the Human Chest Exhibit of plaster models made of human chests from the new born infant through the adult state and models of abnormal tuberculous chests showing that the average healthy chest is flat and wide and that the tuberculous chest is deep and narrow

A. J. COHEN JACOB GERSHON-COHEN and SAMUEL WEIN Eagleville Sanatorium, Eagleville Pa.
